Distributed Operating Systems

Name no more precise →

Interesting/advanced Topics in Operating Systems

- scalability
- systems security
- modeling

Some overlap with "Distributed Systems" (Prof Schill)

In some cases no written material.

Several lectures presented by research-group members.

Strongly requested: register for mailing list

Questions: me or weinhold@os.inf.tu-dresden.de

Distributed OS Hermann Härtig

Scalability in Computer Systems DNS/BIND as a first case study

07/04/13

Outline and Goal of Lectures on Scalability

Outline:

- scalability: terminology, problems
- basic approaches
- case studies

Goal:

 understand some of the important principles how to build scalable systems

Outline and Goal of today's Lecture

Outline:

- scalability ...
- names in Distributed Systems: purposes of naming, terminology
- application of scalability approaches on name resolution

Goal:

- understand some of the important principles how to build scalable systems
- ...using DNS as an example

More Case Studies

- memory consistency
- locks
- file systems
- load balancing (Mosix) and HPC
- RCU (Read Copy Update)

General Definition: Scalability

Scalability:

 the ease with which a system or component can be modified to fit the problem area http://www.sei.cmu.edu/str/indexes/glossary/

Dimensions of Scalability:

- size (more CPUs)
- other resources (memory)
- software (versions, better libs, etc.)
- heterogeneity (different hardware / SW = portability)

More specific: Scalability in Computer Systems

- A system is described as scalable if it remains effective when there is a significant increase in the number of resources and the number of users. (Coulouris, Dollimore, Kindberg: Distributed Systems)
- Scalability [in telecommunication and software engineering] indicates the capability of a system to increase performance under an increased load when resources (typically hardware) are added (Wikipedia)

Scaling down

 a system is scalable if it works well for very large and very small numbers

Definition(Wang, Xu 98):

 A computer system (HW + SW) is called *scalable* if it can scale up (improve its resources) to accommodate ever increasing performance and functionality demand and / or scale down (decrease resources) to reduce cost. Not subject of the course

Prepare for change in functionality

- software engineering
- choose sufficiently large logical resources
- provide hooks for extension

Problems for Scalability in Distrib./Par. Systems

- performance bottlenecks / Amdahl's Law
- failures / abuse
- administration

- f: fraction of computation that can be enhanced
- Speedup: original execution time enhanced execution time
- S: speedup factor for f

• Speedup(f,S) =
$$\frac{1}{\left(1-f+\frac{f}{S}\right)}$$

Consequences: Amdahl's Law

- attack the common case
- if S becomes VERY large, speedup approaches $\frac{1}{(1-f)}$

- interpretation for parallel systems:
 - P: section that can be parallelized
 - 1-P: serial section
 - N: number of CPUs
 - Speedup(P,N) = $\frac{1}{\left(1-P+\frac{P}{N}\right)}$

Principles to achieve Scalability ("RPC")

- identify and address bottlenecks
- partitioning
 - split systems into parts that can operate independently to a large extent
- replication
 - provide several copies of components
 - that are kept consistent eventually
 - that can be used in case of failure of copies
- locality (caching)
 - maintain a copy of information that is nearer, cheaper/faster to access than the original

Principles to achieve Scalability (2)

- specialize functionality/interfaces
- right level of consistency
 - caches, replicates, ... need not always be fully consistent
- lazy information dissemination
- balance load

Some Challenges

- balance load
 - keep load under reasonable threshold
 - at each component
 - in the communication subsystems
 - load balancing can be static or dynamic. Will study a detailed example for dynamic load balancing later(MosiX).
- minimize the delay induced by "RPC"
- prepare for change
- information dissemination
 - choose right degree of consistency

Case study: DNS

some numbers of growth...

Roles: Names, Identifiers, Addresses

- names
 - symbolic
 - have a meaning for people
- identifiers
 - identifies a component (uniquely)
 - are used by programs
- addresses
 - locates a component
 - can change

Name resolution

- name resolution:
 - map symbolic names to objects
 - better: to a set of attributes such as: identifiers, addresses, other names, security properties
- Principle interface:
 - Register (Name, attributes, ...)
 - Lookup (Name) -> attributes

Related

- compilers
 - statically map names to addresses
- dynamic libraries
 - dynamically remap addresses
- port mapper
 - map service to port

Name resolution is a form of dynamic mapping of pathnames to attributes.

Many services, tools, ... provide their own name resolution

- file systems (UNIX: path names to I-Nodes)
- login
- RPC (remote procedure call) systems (portmapper)

Purpose of Directory Services

- integration of name services
- generic name service
- world-wide use of names

Today mostly used:

- email/web
- computer attributes (IP addresses)
- people attributes (certificates, ...)

• ...

A Bit of History

- UUCP/MMDF (cum grano salis):
 - ira!gmdzi!oldenburg!heinrich!user (path to destination)
 - user@ira!heinrich%gmdzi (mixing identifiers and path information)
- ARPA-Net:
 - a single file: hosts.txt
 - maintained at Network Information Center of SRI (Stanford)
 - accessed via ftp
 - TCP/IP in BSD Unix => chaos name collisions, consistency, load
- DNS: Paul Mockapetries (84) ...

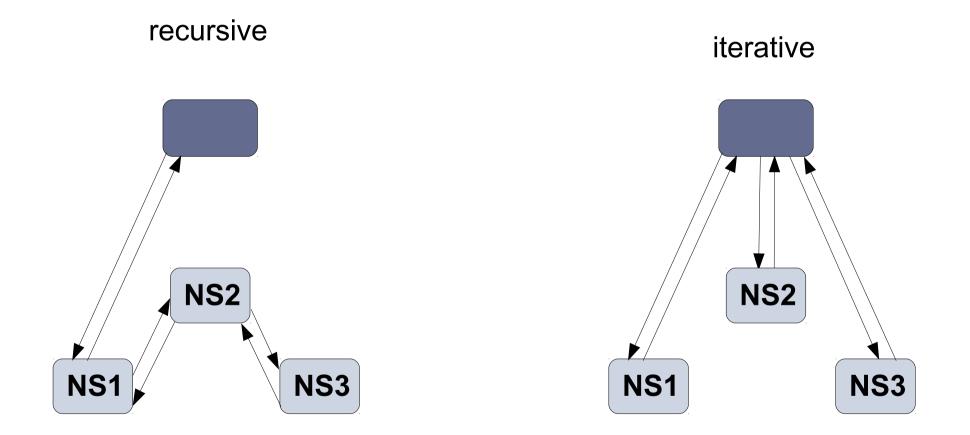

More Terminology

- name space
 - set of names recognized by a name service
- context
 - unit for which a name can be mapped directly
- aliases
 - several names for one object

More Terminology

- naming domain
 - subtree in the hierarchy of DNS contexts
- zone
 - (aka Zone of authority) Subset of a domain over which an authority has complete control. Subzones (starting at apices of a zone) can be delegated to other authorities.
- navigation
 - querying in a set of cooperating name spaces

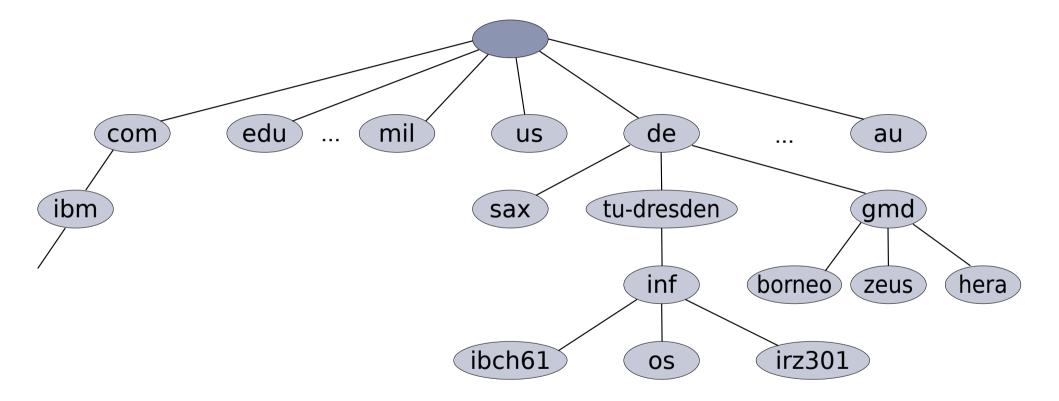

Basic Implementation Variants

Requirements / Properties

- arbitrarily large numbers
- arbitrary units of administration
- long living names, the higher in the hierarchy the longer
- high robustness
- restructuring of name spaces
- consistency
- efficiency

DNS Name Space

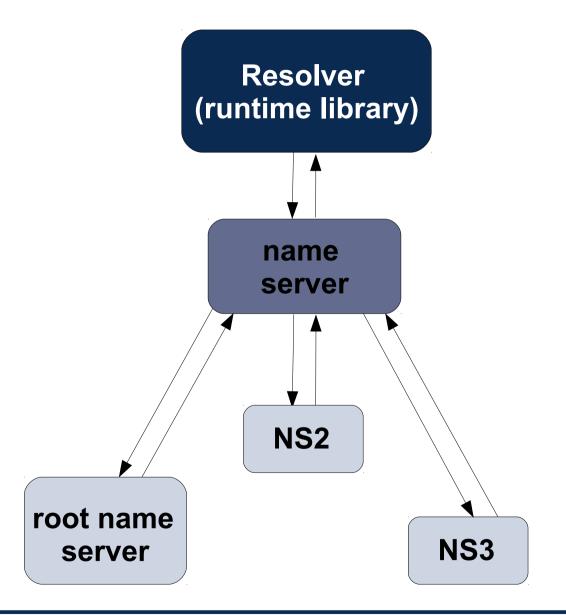

Examples

- inf.tu-dresden.de
- os.inf.tu-dresden.de
- heidelberg.ibm.com

domain computer domain

- ftp ftp.inf.tu-dresden.de
 - DNS: \rightarrow IP address: 141.76.2.3
 - ftp daemon: IP address, port 21
- properties:
 - location independent
 - not very deep

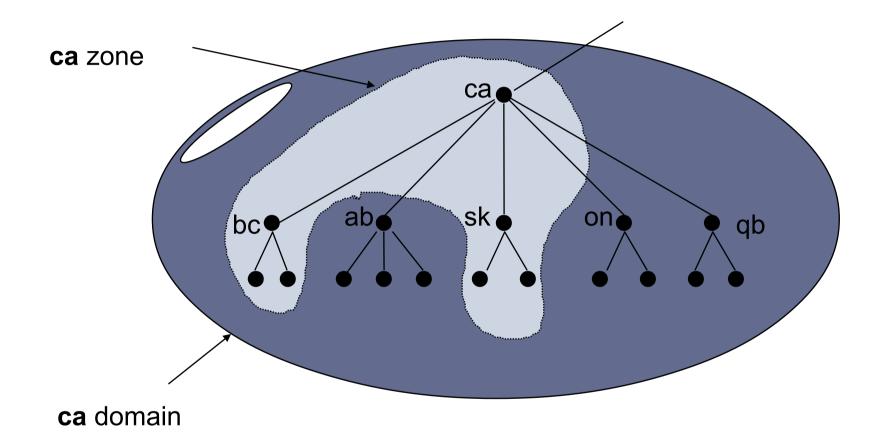

Implementation Structure (BIND)

Partitions: Zones

- Zones:
 - administrative unit
- Name Server:
 - wrong: resolves all names within a zone recursively
 - maps to names and addresses of name servers responsible for sub zones
 - maintains management data
 - process doing the name resolution for one zone
- Resource records (RR):
 - key interface

Partitions: Zones

Example taken from: Coulouris et al., Distributed Systems

Replication

- currently 13 root name servers
- each zone has at least
 - one primary
 - one secondary
 - name server

Caching

- each name server caches resource records
- time to live attribute

authoritative versus non-authoritative answers

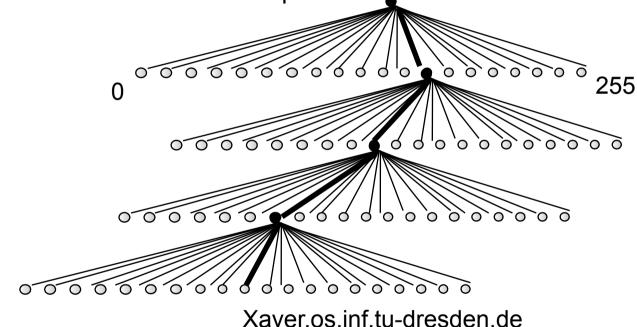

Resource Records

Record type	Interpretation	Content
A	address	IPv4 address
AAAA	address	IPv6 address
NS	Name server	DNS name
CNAME	Symbolic link	DNS name of canonicial name
SOA	Start of authority	Zone-specific properties
PTR	IP reverse pointer	DNS name
HINFO	Host info	Text description of host OS

Reverse Resolution

Example

- IP-Address: 141.76.48.97
 - DNS-Name: 97.48.76.141.in-addr.arpa

Summary: Scalability and DNS

- Good points:
 - replication and caching work well
 - over time, DNS scaled from small numbers to millions
- Bad Points:
 - IP addresses too small
 - no integrated systems security (!!!)
