

**TECHNISCHE  
UNIVERSITÄT  
DRESDEN**

**Faculty of Computer Science** Institute of System Architecture, Operating Systems Group

# **EXERCISE: GETTING STARTED**

**CARSTEN WEINHOLD**

- first contact with a microkernel OS
- getting to know QEMU
- compile Fiasco
- compile minimal system environment
- talk about system booting
- the usual „Hello World“
- review some stuff and play with the system

- developing your own kernel usually requires a dedicated machine
- we will use a virtual machine
- QEMU is open-source software providing a virtual machine by binary translation
- it emulates a complete x86 PC
- available for other architectures as well
- our QEMU will boot from an ISO image

# BOOTING

- Basic Input Output System
- fixed entry point after „power on“ and „reset“
- initializes the CPU in 16-bit real-mode
- detects, checks and initializes some platform hardware (like RAM, PCI, ATA)
- finds the boot device

A dark teal rectangular box with the word "BIOS" in white, bold, sans-serif capital letters. The box has a subtle drop shadow effect.

- first sector on boot disk
- 512 bytes
- contains first boot loader stage and partition table
- BIOS loads code into RAM and executes it
- problem: How to find and boot an OS in 512 bytes?

A dark teal rectangular box with the word "BIOS" in white, bold, sans-serif capital letters. The box has a subtle drop shadow effect.

Physical Memory

- popular boot loader
- used by most (all?) Linux distributions
- uses a two-stage-approach
  - first stage fits in one sector
  - has hard-wired sectors of second stage files
  - second stage can read common file systems

**Boot Loader**

**BIOS**

- second stage loads a menu.lst config file to present a boot menu
- from there, you can load your kernel
- supports loading multiple modules
- files can also be retrieved from network

**Boot Loader**

**BIOS**

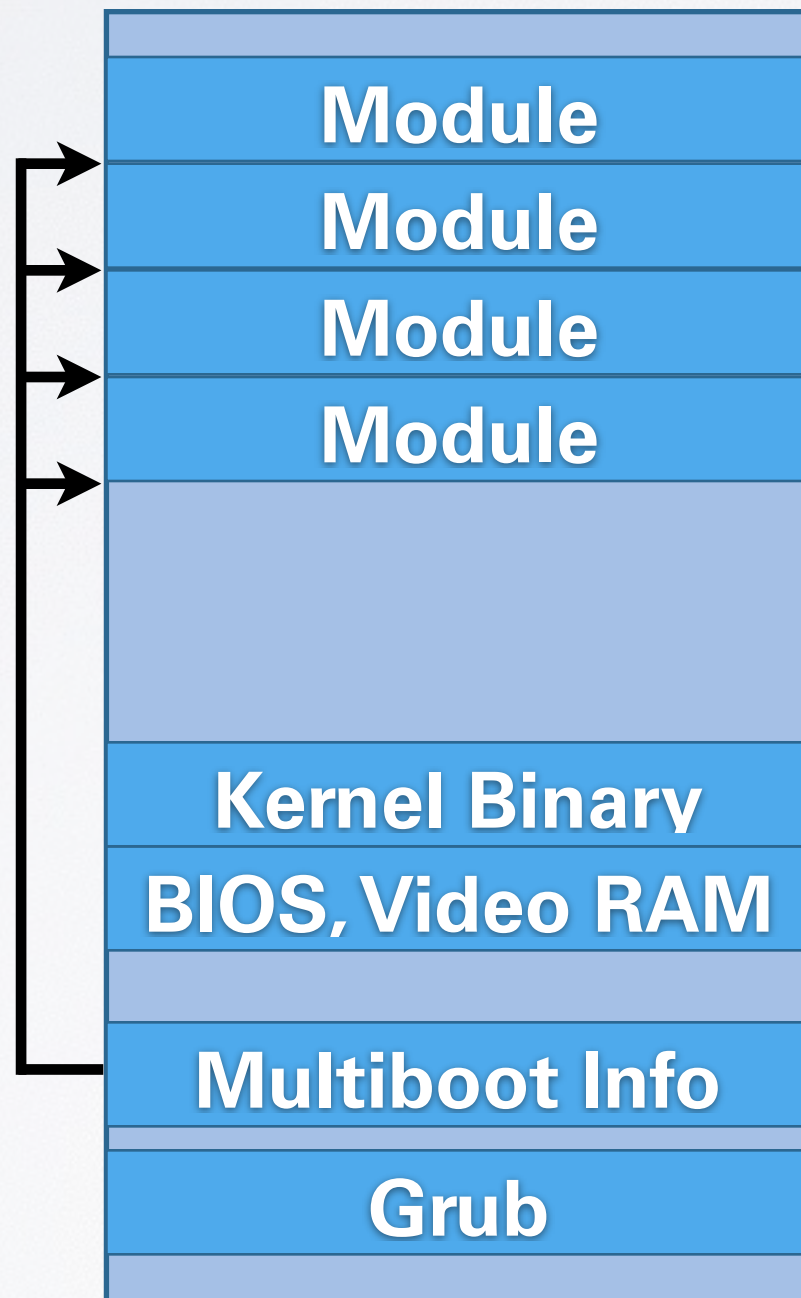

- switches CPU to 32-bit protected mode
- loads and interprets the „kernel“ binary
- loads additional modules into memory
- sets up multiboot info structure
- starts the kernel

**Boot Loader**

**BIOS**

Physical Memory

**Boot Loader**

**BIOS**

- our modules are ELF files:  
executable and linkable  
format
- contain multiple sections
  - code, data, BSS
- bootstrap interprets the ELF  
modules
- copies sections to final  
location in physical memory

**Bootstrap**

**Boot Loader**

**BIOS**

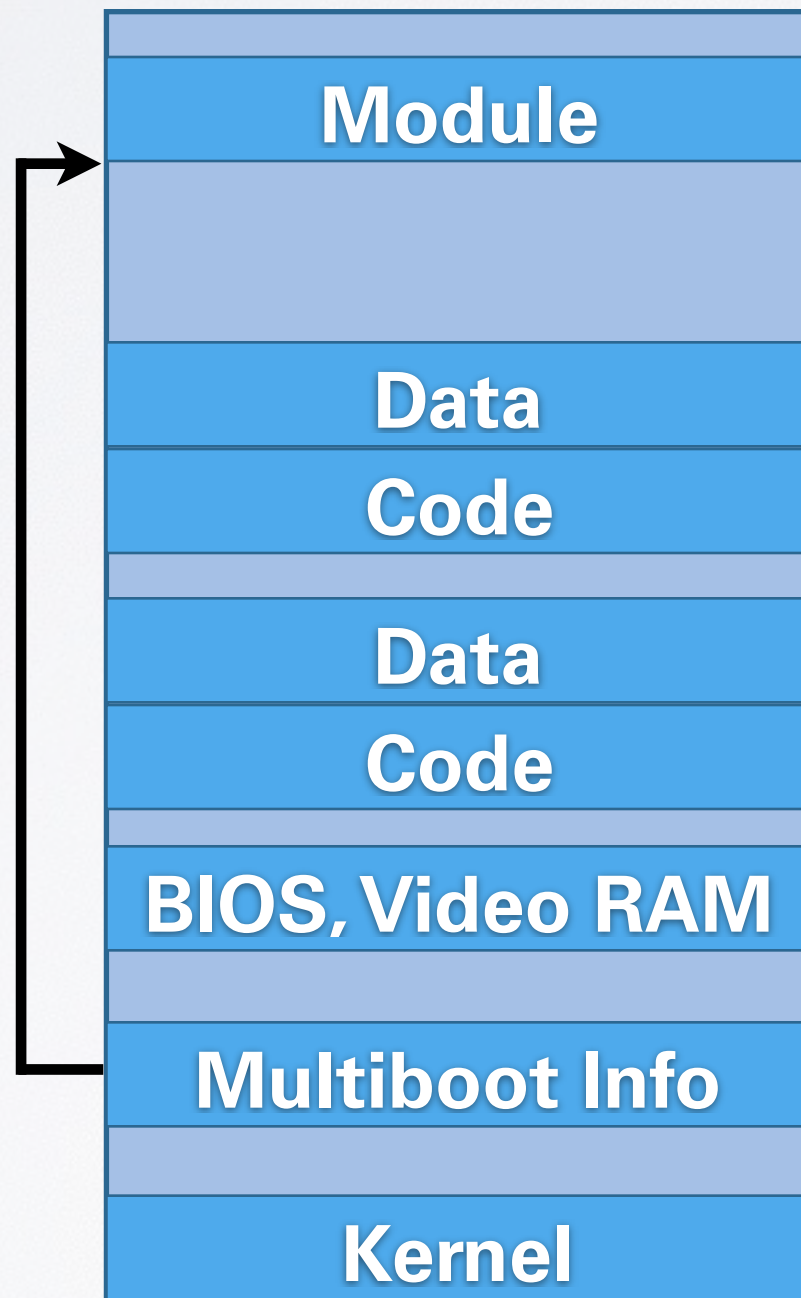

- actual kernel is the first of the modules
- must know about the other modules
- bootstrap sets up a kernel info page
  - contains entry point and stack pointer of sigma0 and moe
- passes control to the kernel

**Bootstrap**

**Boot Loader**

**BIOS**

Physical Memory

- initial kernel code
- basic CPU setup
  - detecting CPU features
  - setup various CPU-tables
- sets up basic page table
- enables virtual memory mode
- runs the actual kernel code

**Kernel Loader**

**Bootstrap**

**Boot Loader**

**BIOS**

# MEMORY LAYOUT

Virtual Memory

- sets up kernel structures
- sets up scheduling timer
- starts first pager
- starts first task
- starts scheduling
- scheduler hands control to userland for the first time

- is the first pager in the system
- initially receives a 1:1 mapping of physical memory
- ... and other platform-level resources (IO ports)
- sigma0 is the root of the pager hierarchy
- pager for moe

- manages initial resources
  - namespace
  - memory
  - VESA framebuffer
- provides logging facility
- mini-filesystem for read-only access to boot-modules

- script-driven loader for further programs
  - startup-scripts written in Lua
- additional software can be loaded by retrieving binaries via disk or network drivers
- ned injects a common service kernel into every task

# Setup

- download the source tarball from <https://os.inf.tu-dresden.de/Studium/KMB/WS2015/Exercise1.tar.bz2>
- unpack the tarball
  - it comes with a working directory
  - `cd` in there and have a look around
- initialize the environment with `make setup` in the toplevel directory you unpacked

# Compiling the System

- run `make` within the toplevel directory

# Test-Driving QEMU

- create a bootable ISO image
  - the `iso` subdirectory is for the ISO's content
  - run `isocreator` from `src/14/tool/bin` on this directory
- your ISO will contain a minimal grub installation
- launch QEMU with the resulting ISO:  
`qemu-system-i386 -cdrom boot.iso`

# Booting Fiasco

- copy some files to the ISO directory
  - `fiasco` from the Fiasco build directory  
`obj/fiasco/ia32/`
  - `bootstrap` from  
`obj/14/x86/bin/x86_586/`
  - `sigma0`, `moe`, `14re` and `ned` from  
`obj/14/x86/bin/x86_586/14f/`

# Booting Fiasco

- edit `iso/boot/grub/menu.lst`:  
    `title Getting Started`  
    `kernel /bootstrap -modaddr 0x01100000`  
    `module /fiasco`  
    `module /sigma0`  
    `module /moe`  
    `module /l4re`  
    `module /ned`
- rebuild the ISO and run `qemu`

# Preparing for Hello

- create the file `hello.lua` in the `iso` directory with this content:

```
L4.default_loader:start({},  
"rom/hello");
```

- pass `ned` this new startup script
  - add this line to `menu.lst`:  
`module /hello.lua`
  - pass `rom/hello.lua` as parameter to `moe`
- load the future `hello` module in `menu.lst`

# Exercise 1: Hello World

- create a directory for your hello-project
- create a Makefile with the following content:

```
PKGDIR          ?= .
L4DIR           ?= absolute path to
                  L4 source tree
OBJ_BASE        = absolute path to L4 build tree
TARGET          = hello
SRC_C           = hello.c
include $(L4DIR)/mk/prog.mk
```

- fill in `hello.c` and compile with `make`
- run in `qemu`

# Exercise 2: Ackermann Function

- write a program that spawns six threads
  - you can use pthreads in our system
  - add the line  
`REQUIRES_LIBS = libpthread`  
to your `Makefile`
- each thread should calculate one value  $a(3, 0..5)$  of the Ackermann function:
  - $a(0, m) = m + 1$
  - $a(n, 0) = a(n - 1, 1)$
  - $a(n, m) = a(n - 1, a(n, m - 1))$
