“TRUSTED” COMPUTING

DISTRIBUTED OPERATING SYSTEMS

Hermann Härtig
Summer 2015

Understand principles of:

- Authenticated booting, relation to (closed) secure booting
- Remote attestation
- Sealed memory
- Dynamic root of trust, late launch
- Protection of applications from the OS
- Point to variants of implementation in HW (TPM, SGX)

Beware of terminology changes !

Non-Goal:

- Lots of TPM, TCG, Trustzone, SGX details
→ read the documents once needed

- Secure Booting
- Authenticated Booting
- (Remote) Attestation
- Sealed Memory
- Late Launch / dynamic root of trust
- Trusted Computing (Group) / Trusted Computing Base

- Attention: terminology has changed

Trusted Computing Base (TCB)

- The set off all components, hardware, software, procedures, that must be relied upon to enforce a security policy.

Trusted Computing (TC)

- A particular technology comprised of authenticated booting, remote attestation and sealed memory.

- Can running certain Software be prevented?
- Which computer system do I communicate with ?
- Which stack of Software is running?
 - In front of me?
 - On my server somewhere?
- Restrict access to certain secrets (keys) to certain software?
- Protect an application against the OS

Digital Rights Management:

- Provider sells content
- Provider creates key, encrypts content
- Client downloads encrypted content, stores on disk
- Provider sends key, but needs to ensure that only specific SW can use it
- Has to work also when client is off line
- PROVIDER DOES NOT TRUST CUSTOMER

Virtual machine provided by cloud

- Client buys Cycles + Storage (Virtual machine)
- Client provides its own operating system
- Needs to ensure that provided OS runs
- Needs to ensure that provider cannot access data
- **CUSTOMER DOES NOT TRUST PROVIDER**

Industrial Plant Control (Uranium enrichment)

- Remote Operator sends commands, keys
- Local operator occasionally has to run test SW, update to new version, ...
- Local technicians are not Trusted

Anonymity Service

- Intended to provide anonymous communication over internet
- Legal system can request introduction of trap door (program change)
- Anonymity-service provider not trusted

Measuring

- “process of obtaining metrics of platform characteristics”
- Example for metric: Hash- Codes of SW

Attestation

- “vouching for accuracy of information”

Sealed Memory

- binding information to a configuration

Principle Method:

separate critical Software

rely on small Trusted Computing Base

- Small OS kernels

micro kernels, separation kernels,

- Hardware

SK_{priv} SK_{pub} Asymmetric key pair of some entity S

- $\{ M \}_X K_{priv}$ Digital Signature for message M
using the private key of signer X
- $\{ M \}_Y K_{pub}$ Message encrypted using public
concellation key of Y
- $H(M)$ Collision-Resistant Hash Function
- Certificate by authority Ca :
 $\{ ID, SK_{pub}, \text{other properties} \} CaK_{priv}$

Note:

- “{ M }SkprivDigital Signature”
is short for: $\text{encrypt}(H(M), \text{Skpriv})$
- “{ M }Skpub Message concealed ...”
does not necessarily imply
public key encryption for full M
(rather a combination of
symmetric and asymmetric methods)

Program vendor: Foosoft FS

Two ways to identify Software: Hash / public key

- $H(\text{Program})$
- $\{\text{Program, ID- Program}\}_{\text{FSKpriv}}$
use FSKpub to check
the signature must be made available,
e.g. shipped with the Program
- The „ID“ of SW must be known.

CPU

Memory

Non-Volatile Memory
(NVM):

Platform Configuration Regs
(PCR):

TRB
Conceptual
View

- Read-Only Memory
- H(OS) in NVM preset by manufacturer
 - load OS- Code
 - compare H(loaded OS code) to preset H(OS)
 - abort if different
- FSKpub in NVM preset by manufacturer
 - load OS- Code
 - check signature of loaded OS-Code using FSKpub
 - abort if check fails

Steps:

1. Preparation by TRN and OS Vendors
2. Booting & "Measuring"
3. Remote attestation

CPU

Memory

NVM:

PCR:

TRB
Conceptual
View

NVM:

PCR:

TRB generates key pair:
„Endorsement Key“ (EK)
stores in TRB NVM
emits EKpub

TRB generates key pair:
„Endorsement Key“ (EK)
stores in TRB NVM
emits EKpub

- TRB vendor certifies:
{“a valid EK”, EKpub}TRB_VKpriv
- OS-Vendor certifies:
{„a valid OS”, H(OS)}OS_VKpriv
- serve as identifiers:
EKpub and H(OS)

TRB:

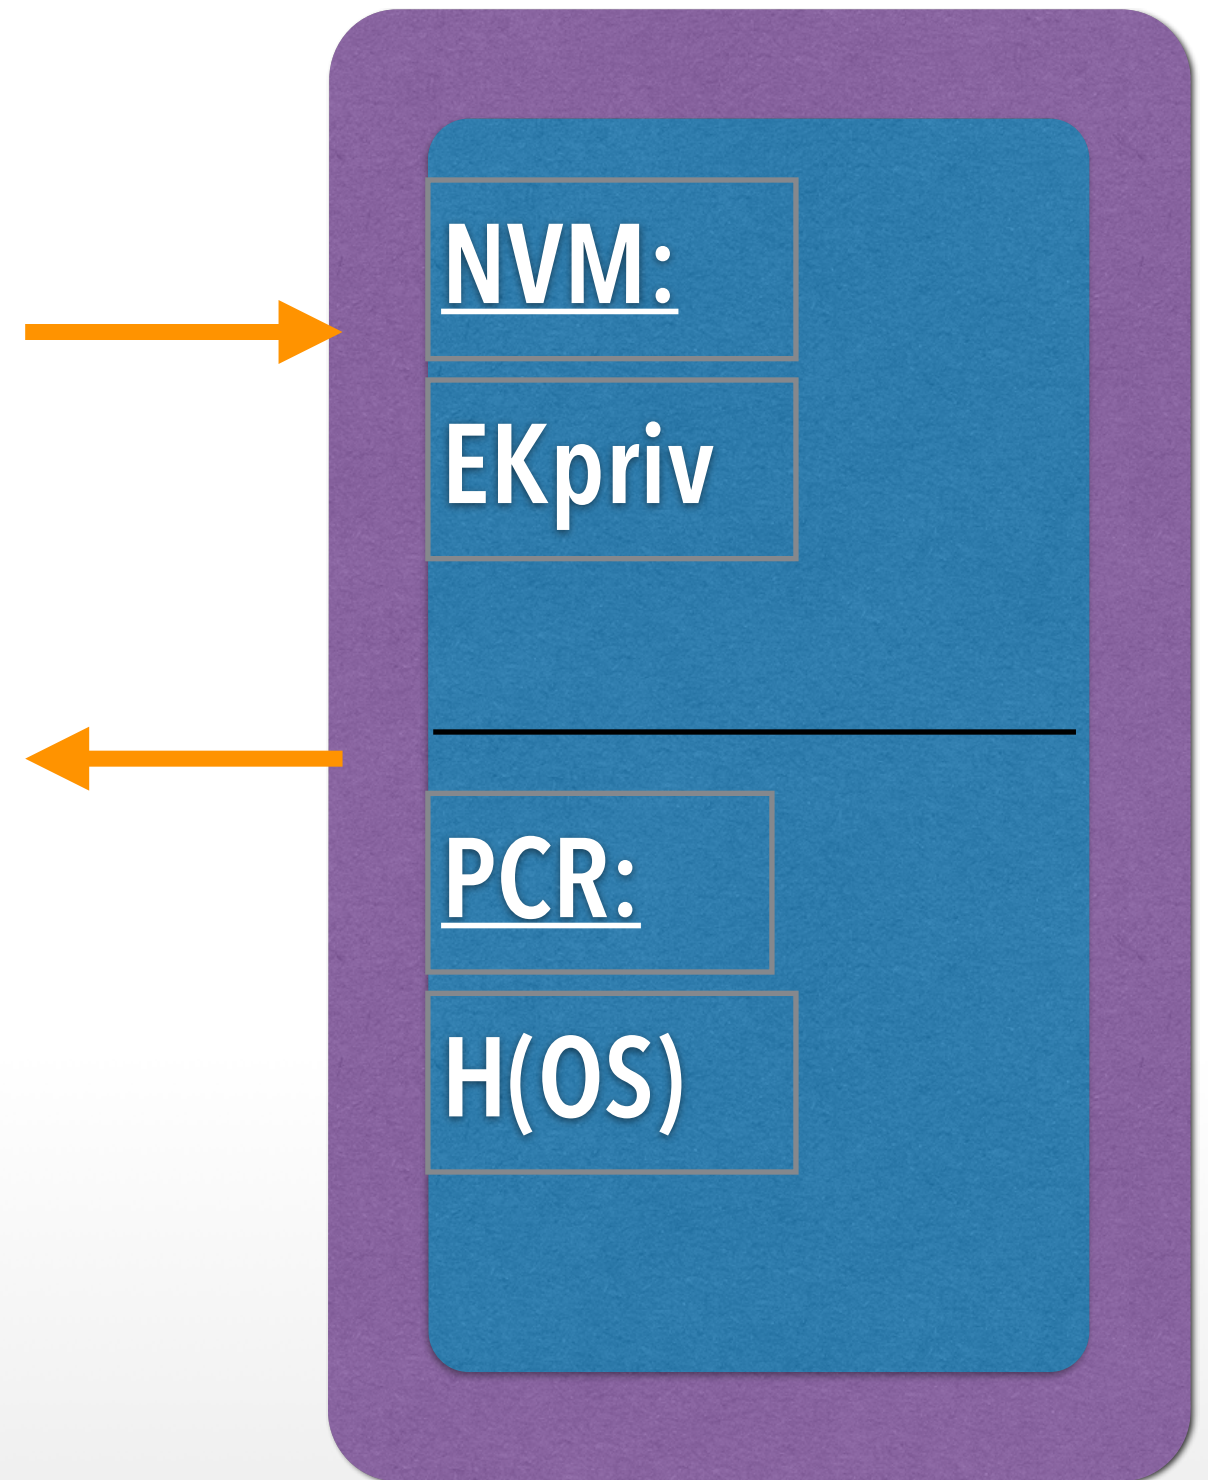

- measures OS code
H(OS)
- resets TRB
- stores H(OS) in PCR 

PCR not (directly) writable
by OS
more later

Challenge:
send NONCE

Response:
{NONCE', PCR}EKpriv

- boot Linux
 - challenge
 - ← response "Linux"
- reboot Windows
 - send data

add one step of indirection:

create keypairs at each reboot

At booting, TRB :

- computes $H(OS)$ and stores in PCR
- creates 2 keypairs for the booted, "active" OS :
 - ActiveOSAuthK /* for Authentication
 - ActiveOSConsk /* for Concellation
- certifies: $\{ \text{ActiveOSAuthKpub}, \text{ActiveOSConskpub}, H(OS) \} \text{EKpriv}$
- hands over ActiveOSKeys to booted OS

Remote Attestation:

- Challenge: nonce
- Active OS generates response:
{ ActiveOSConsKpub, ActiveOSAuthKpub,
H(OS)}EKpriv /* see previous slide
{nonce'} ActiveOSAuthKpriv

Secure channel:

{ message } ActiveOSConsKpub

- TRB can protect: EK, PCR
OS can protect: "Active OS keys"
- Rebooting destroys content of
 - PCR
 - Memory Holding "Active OS keys"

2 Problems:

- Very large Trusted Computing Base for Booting (Drivers etc)
- Remote attestation of one process (leaf in tree)

“Extend” Operation:

- stack: $PCR_n = H(PCR_{n-1} \parallel \text{next-component})$
- tree: difficult (unpublished ?)

Key pairs per step:

- OS controls applications →
generate key pair per application
- OS certifies
 - { Application 1, App1Kpub } ActiveOSKpriv
 - { Application 2, App2Kpub } ActiveOSKpriv

Problem: huge Software to boot system !!!

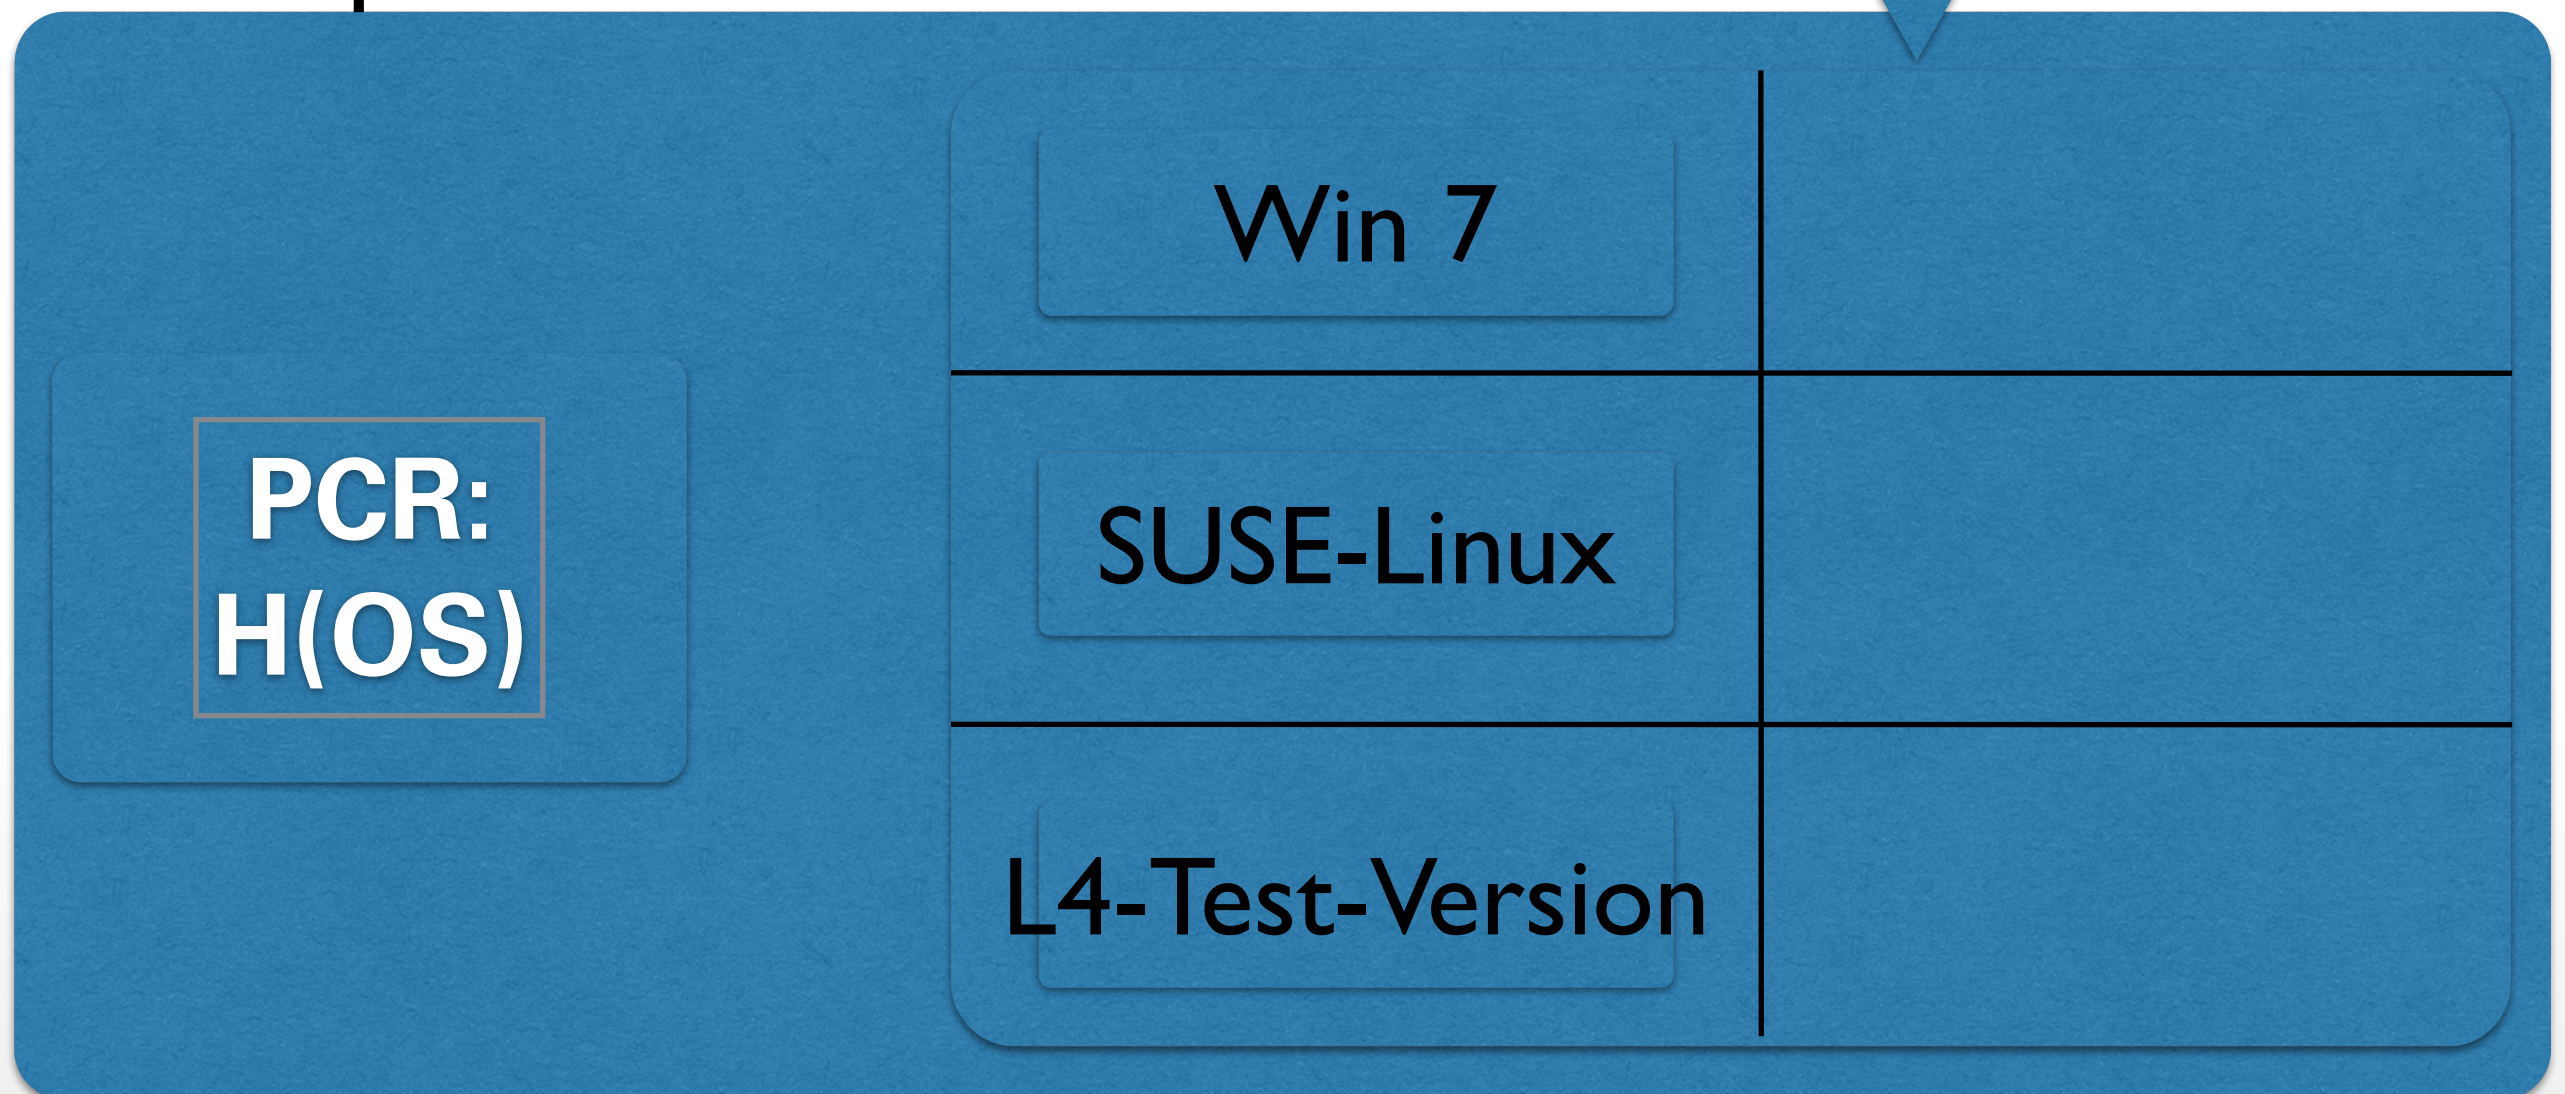

- Use arbitrary SW to start system and load all SW
- provide specific instruction to enter "secure mode"
 - set HW in specific state (stop all processors, IO, ...)
 - Measure "root of trust" SW
 - store measurement in PCR
- AMD: "skinit" (Hash) arbitrary root of trust
- Intel: "senter" (must be signed by chip set manufacturer)

Problem:

- Send information using secure channels
- Bind that information to Software configuration
- Work offline:
How to store information in the absence of communication channels?
- For example DRM:
bind encryption keys to specific machine,
specific OS

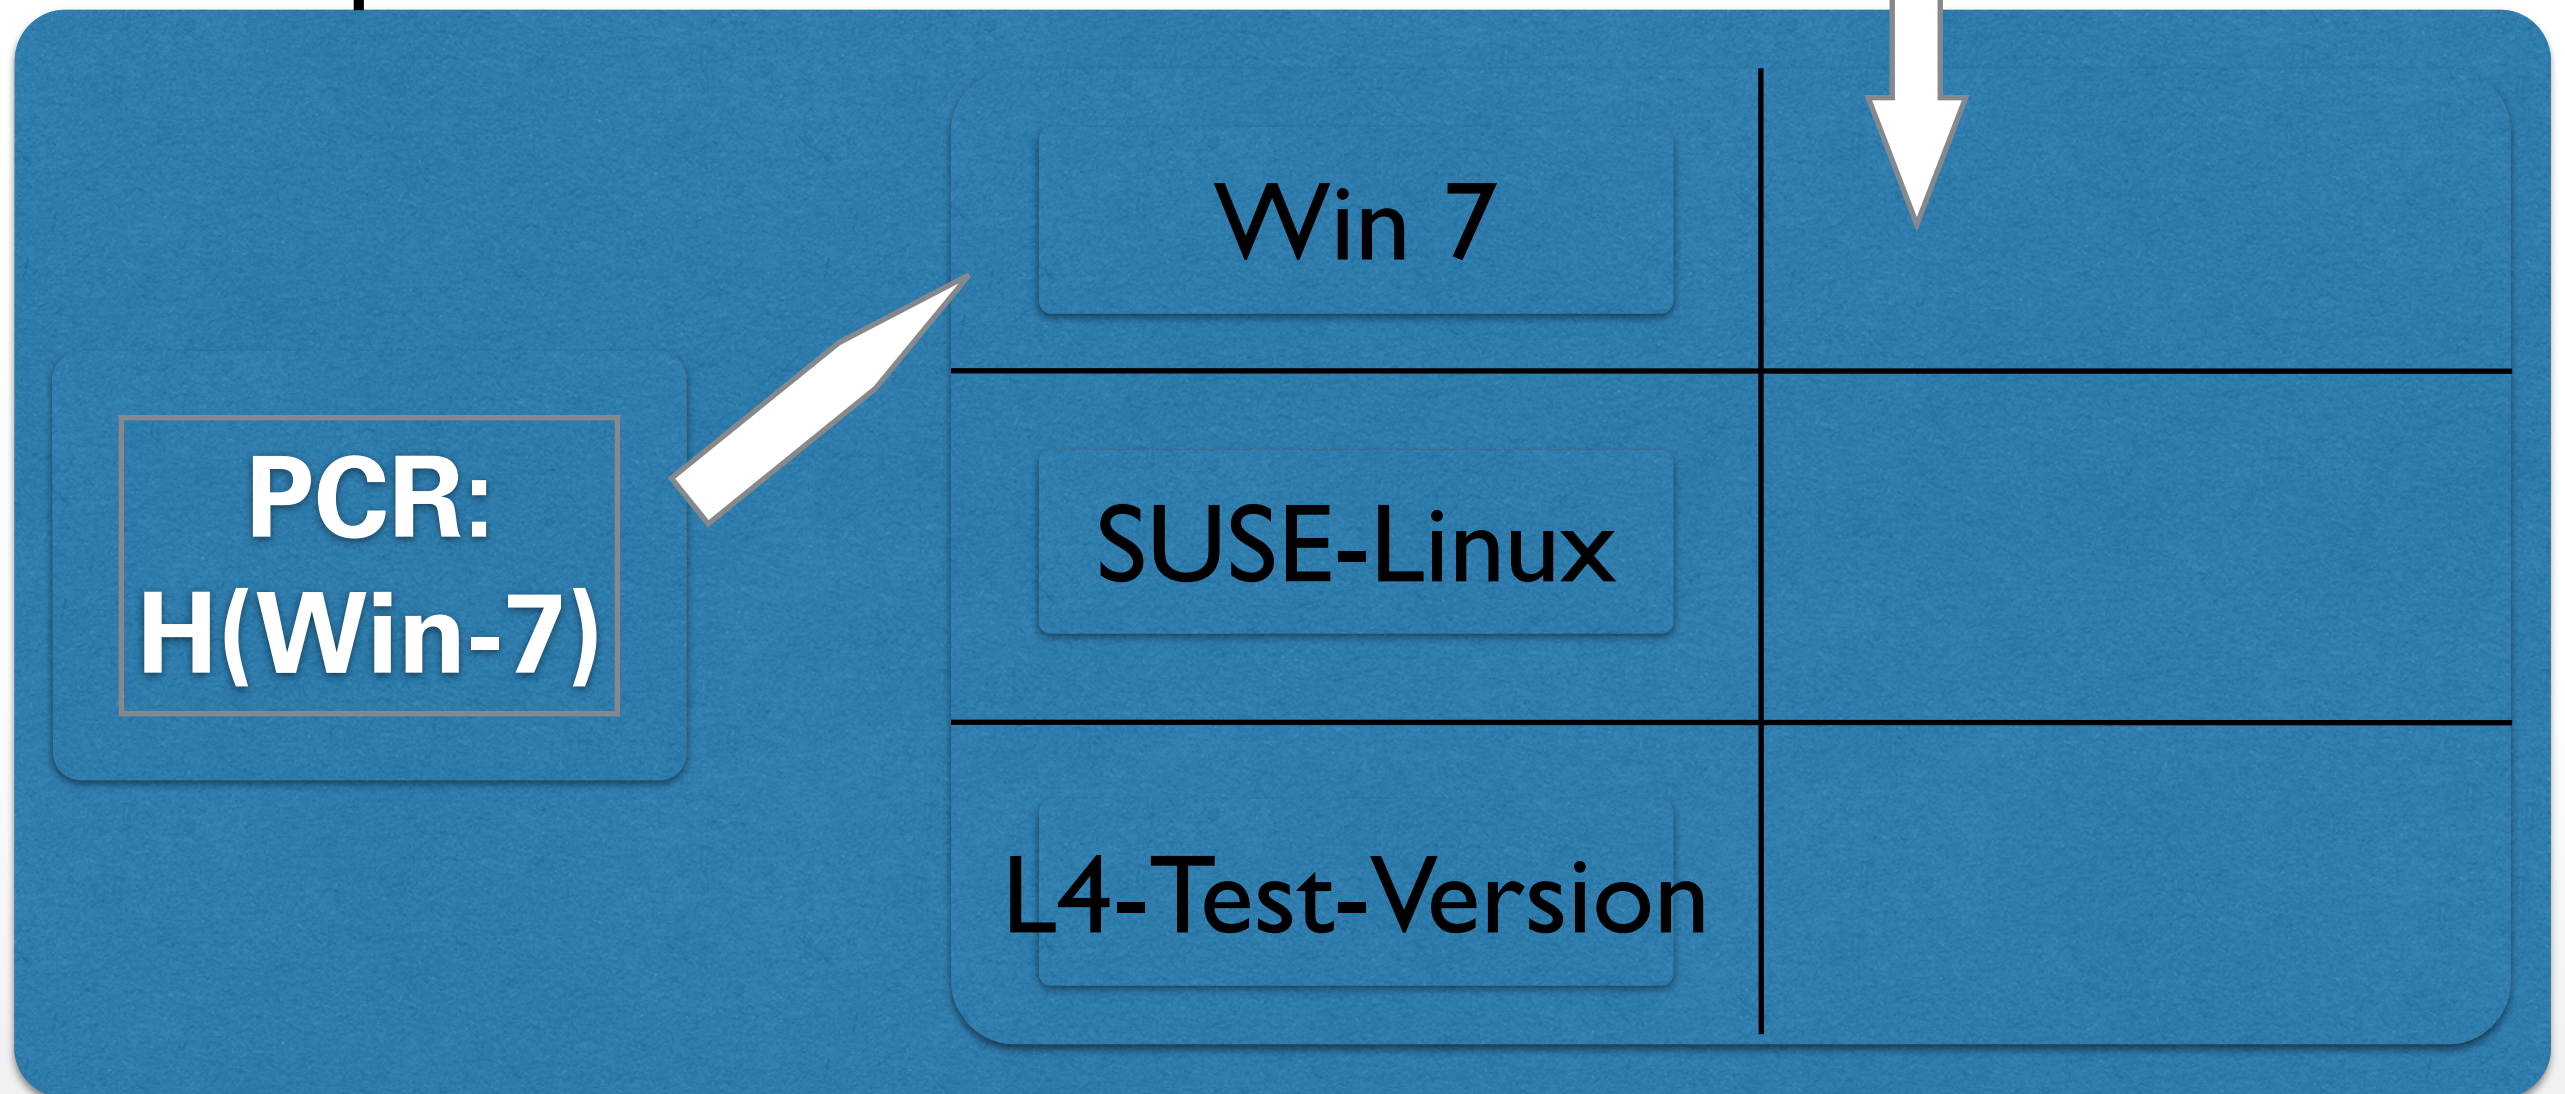

Add / delete entry
Read / write

Tamper-resistant black box

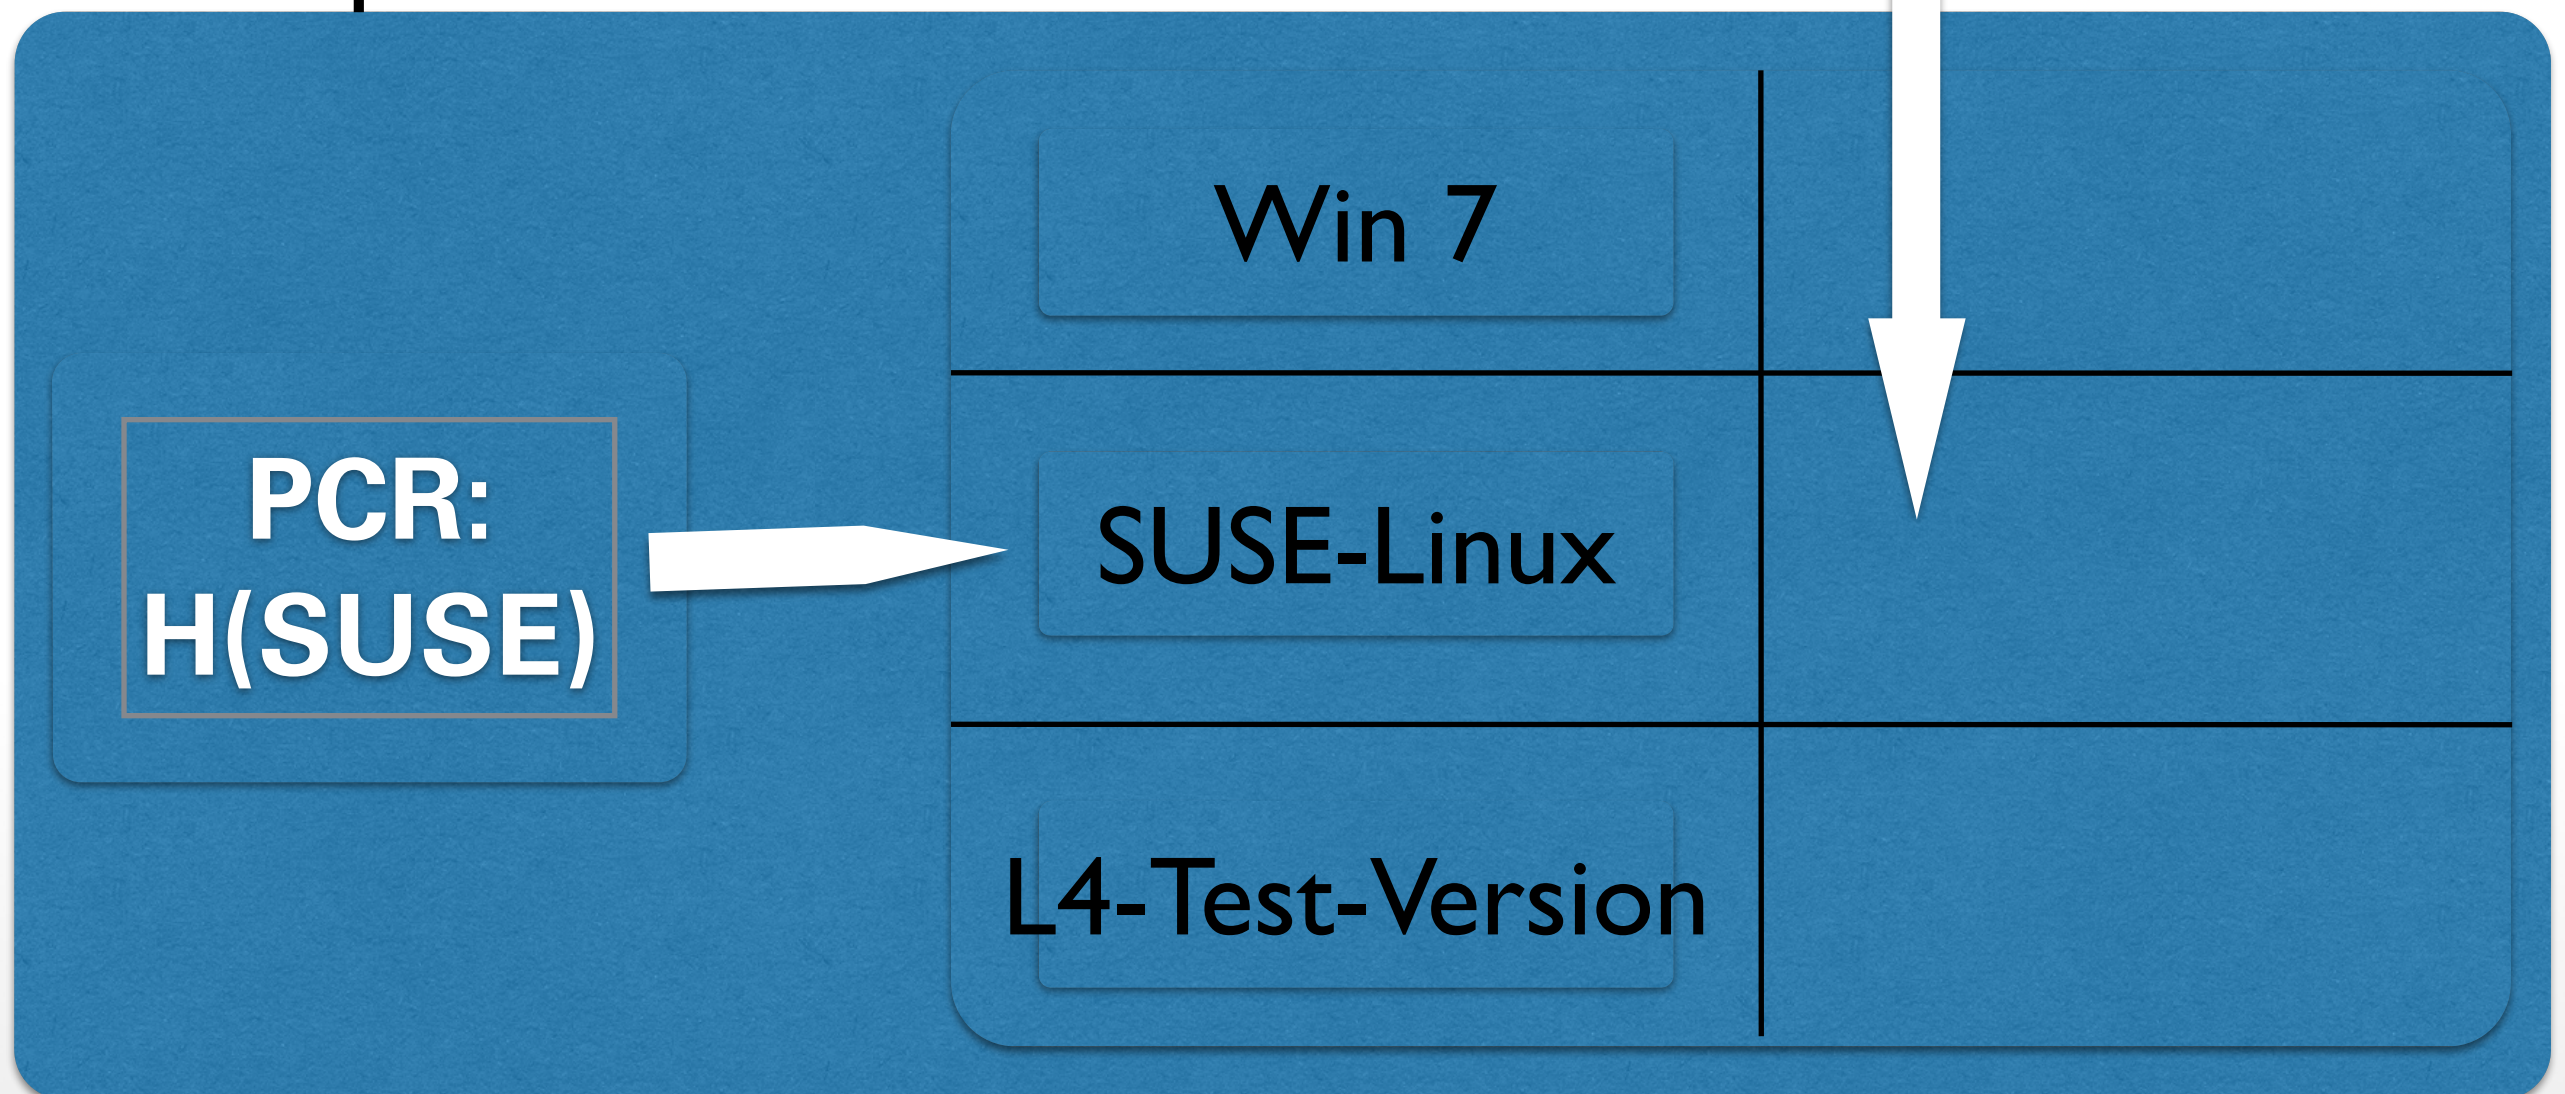

Tamper-resistant black box

Add / delete entry
Read write

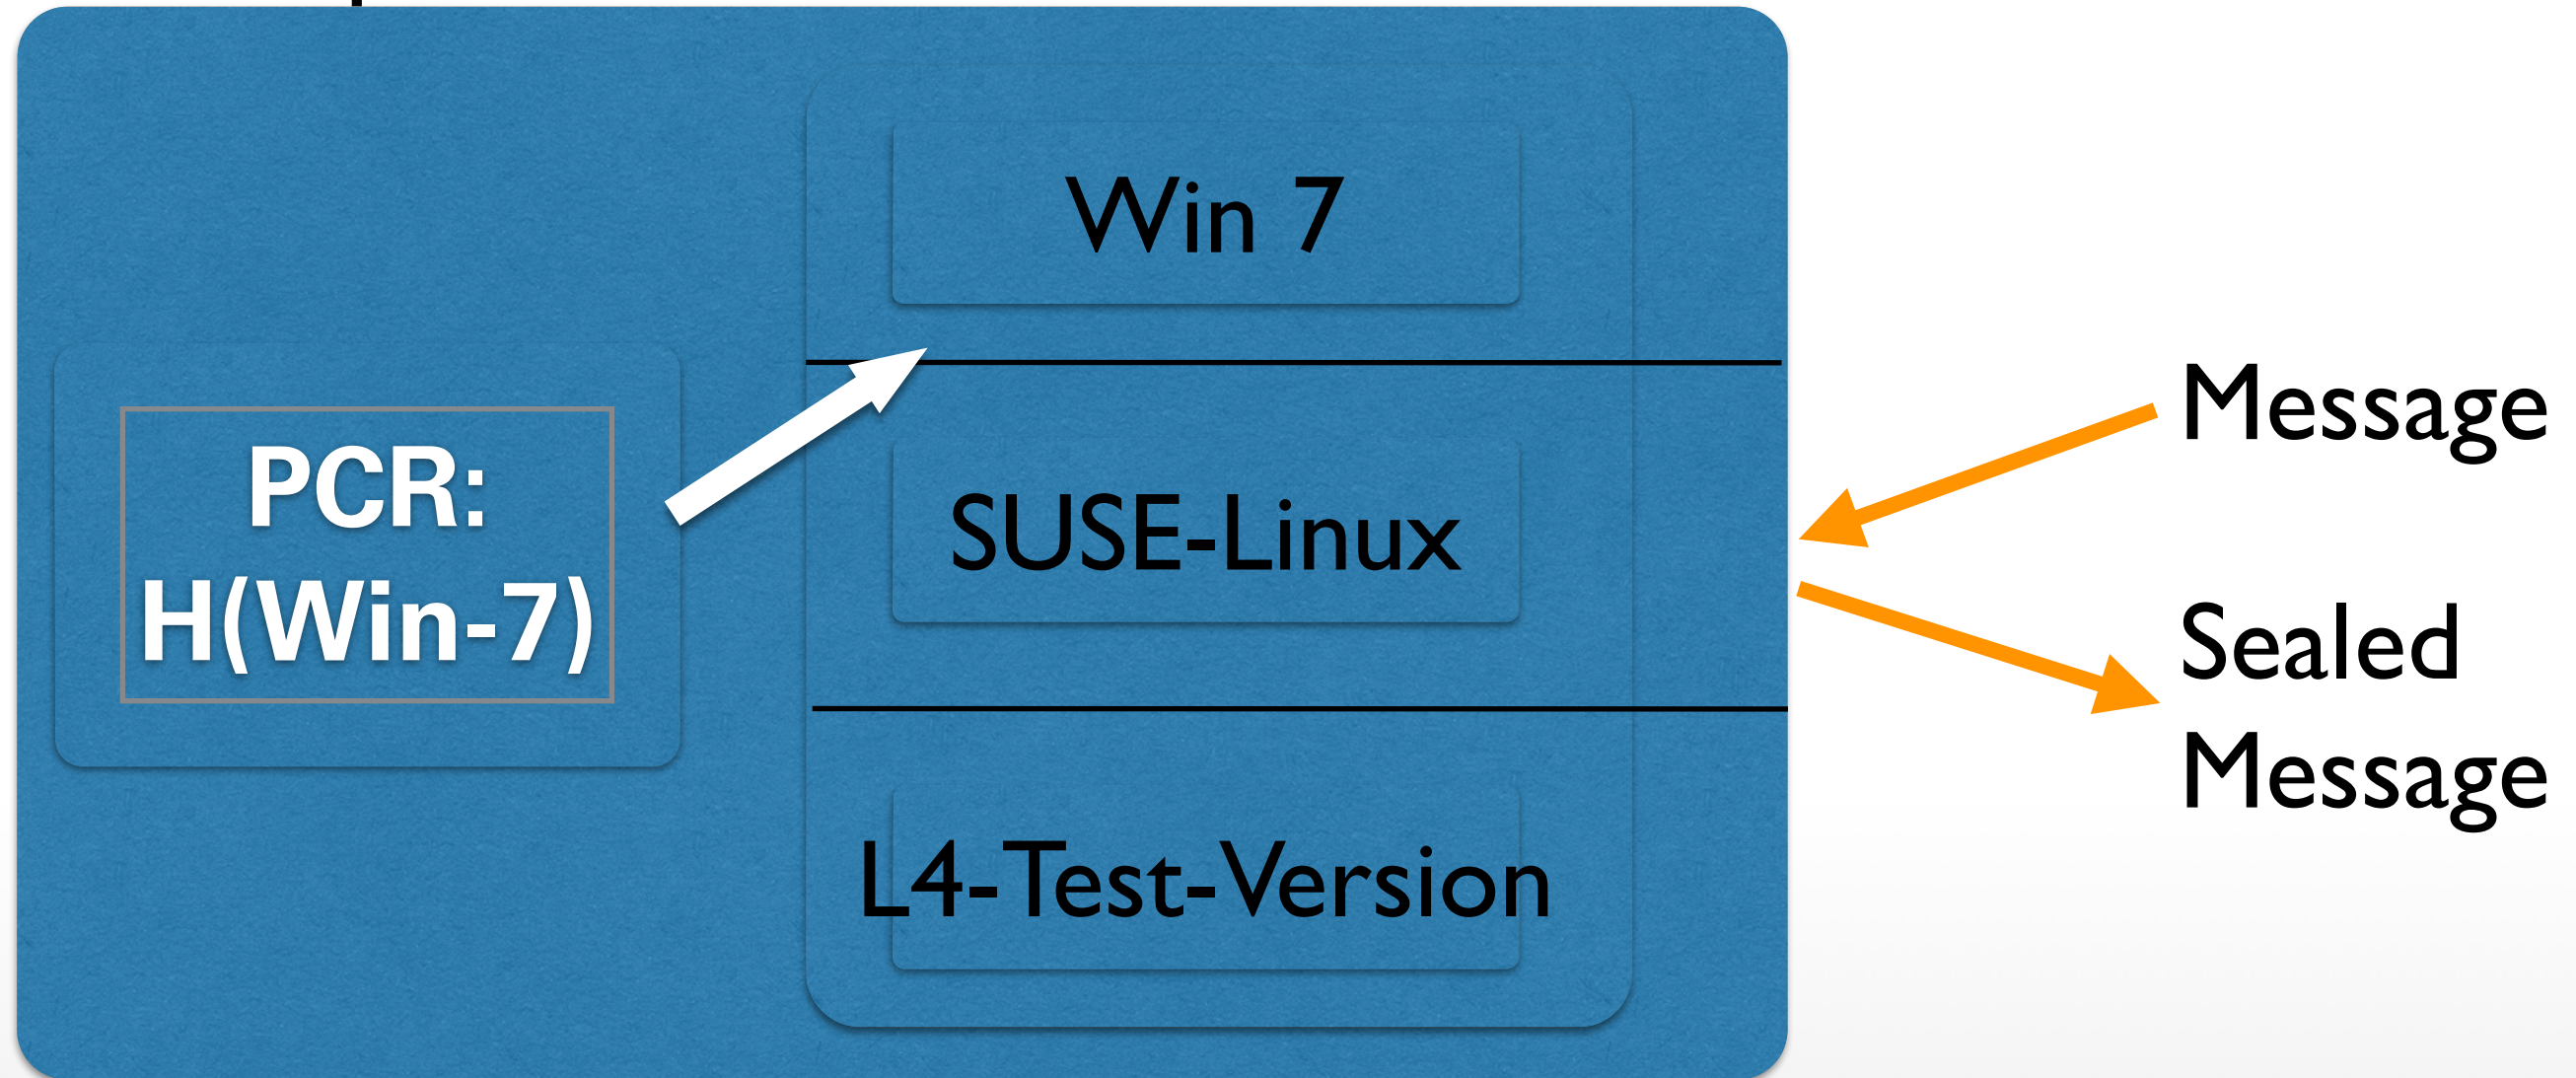

Add / delete entry
Read write

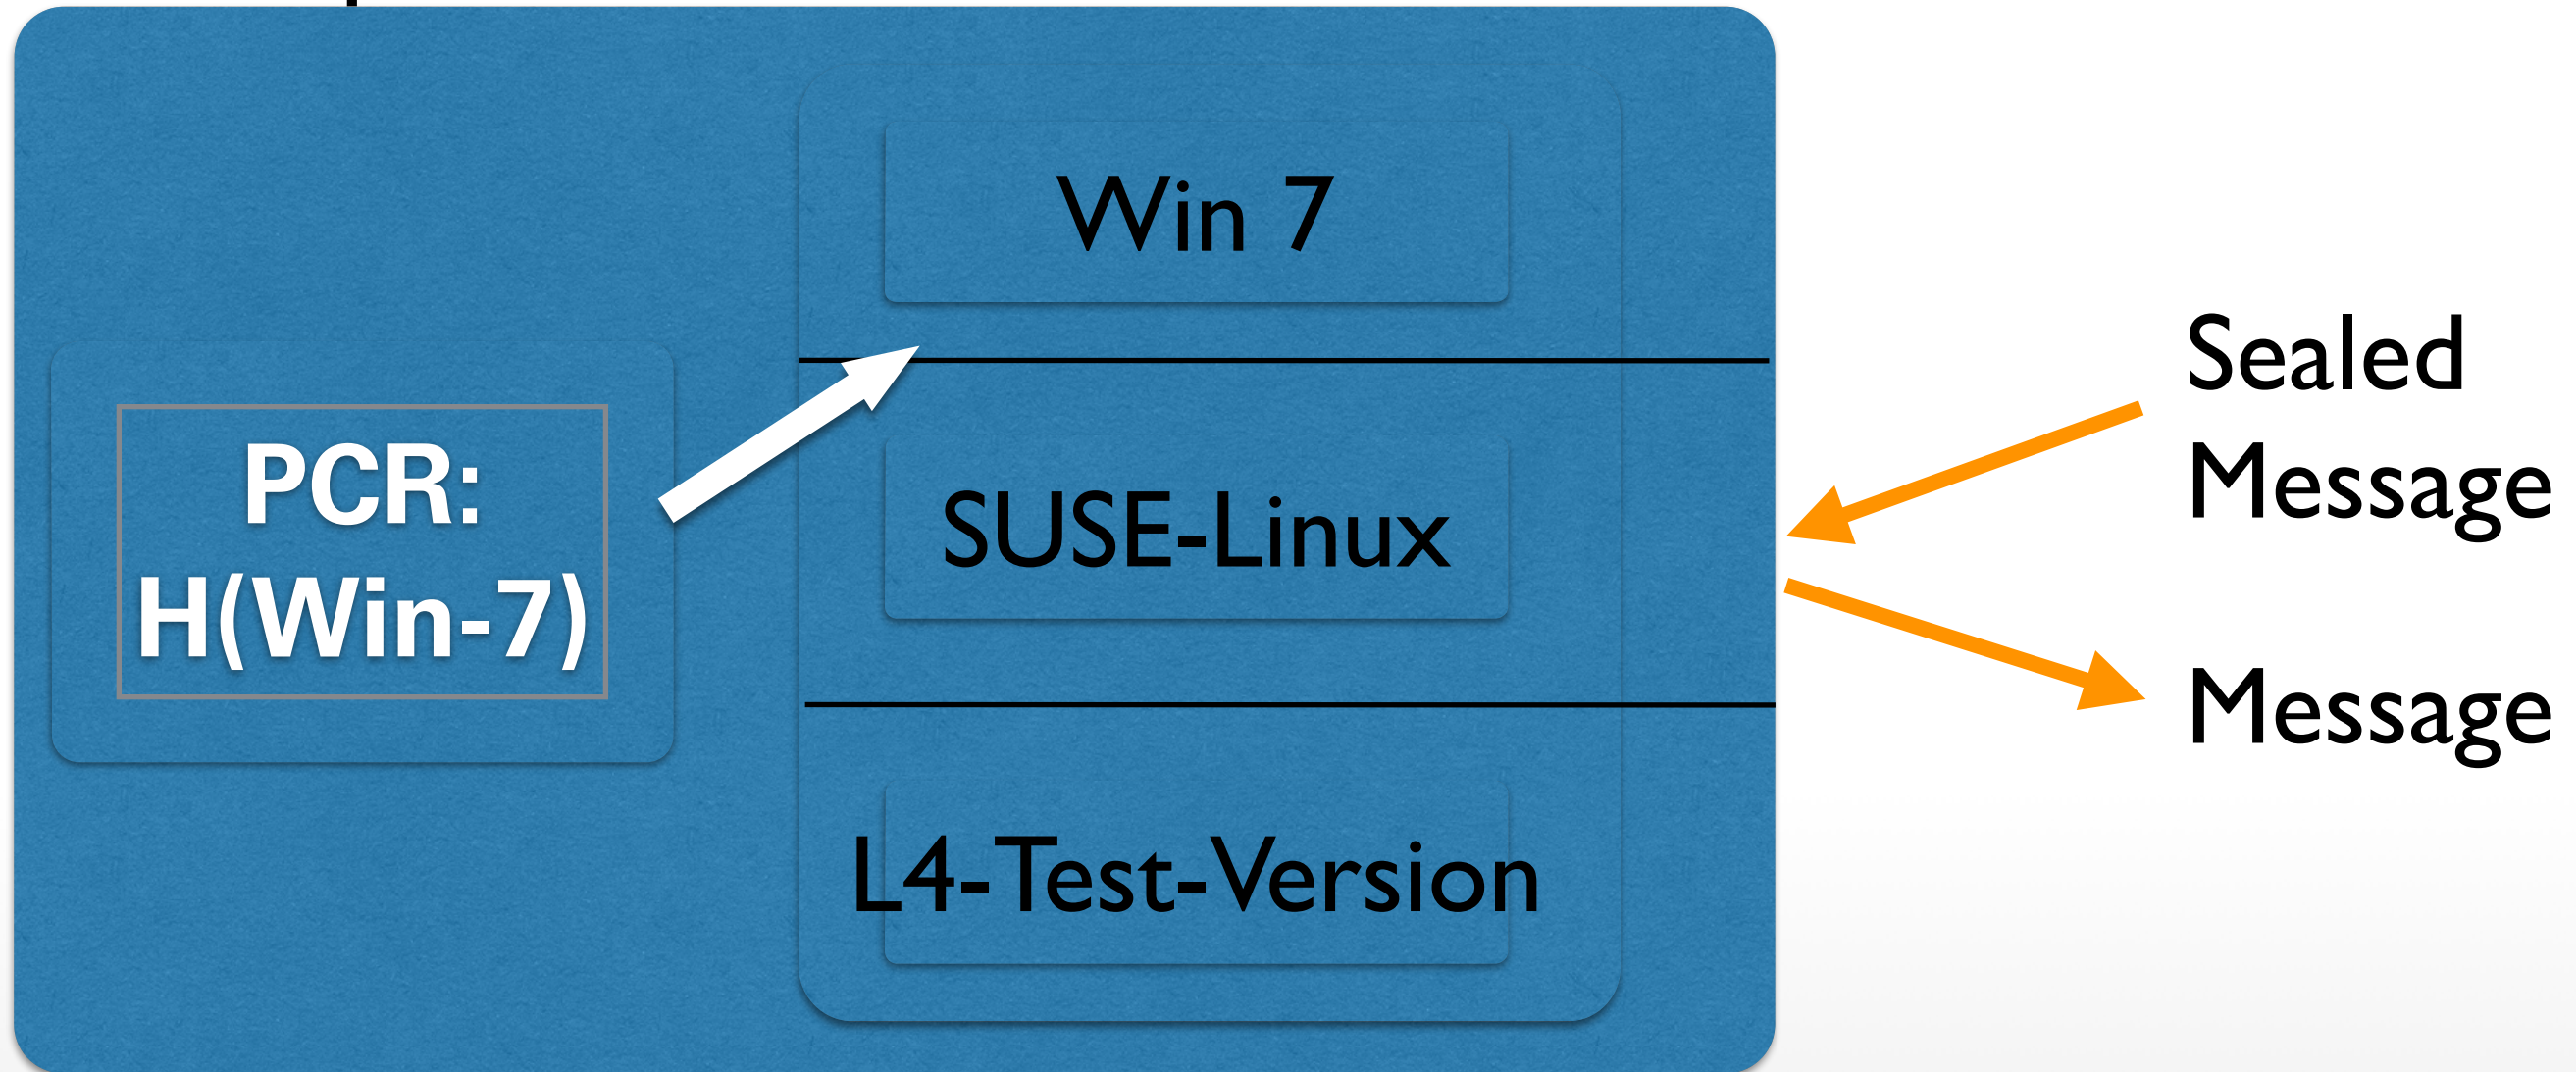

Tamper-resistant black box

Tamper-resistant black box

Tamper-resistant black box

TRB generates symmetric
Storage Key (S)
never leaves chip

Seal(message):

```
encrypt("PCR, message", S) → "sealed_message";  
emit sealed_message
```

Unseal(sealed_message):

```
decrypt(sealed_message, S) →  
"SealTime_PCR, message";
```

```
If SealTime_PCR == PCR  
  then emit message  
  else abort
```

Seal(message, FUTURE_Config):

```
encrypt("FUTURE_Config, message", S)  
    → "sealed_message";  
emit sealed_message
```

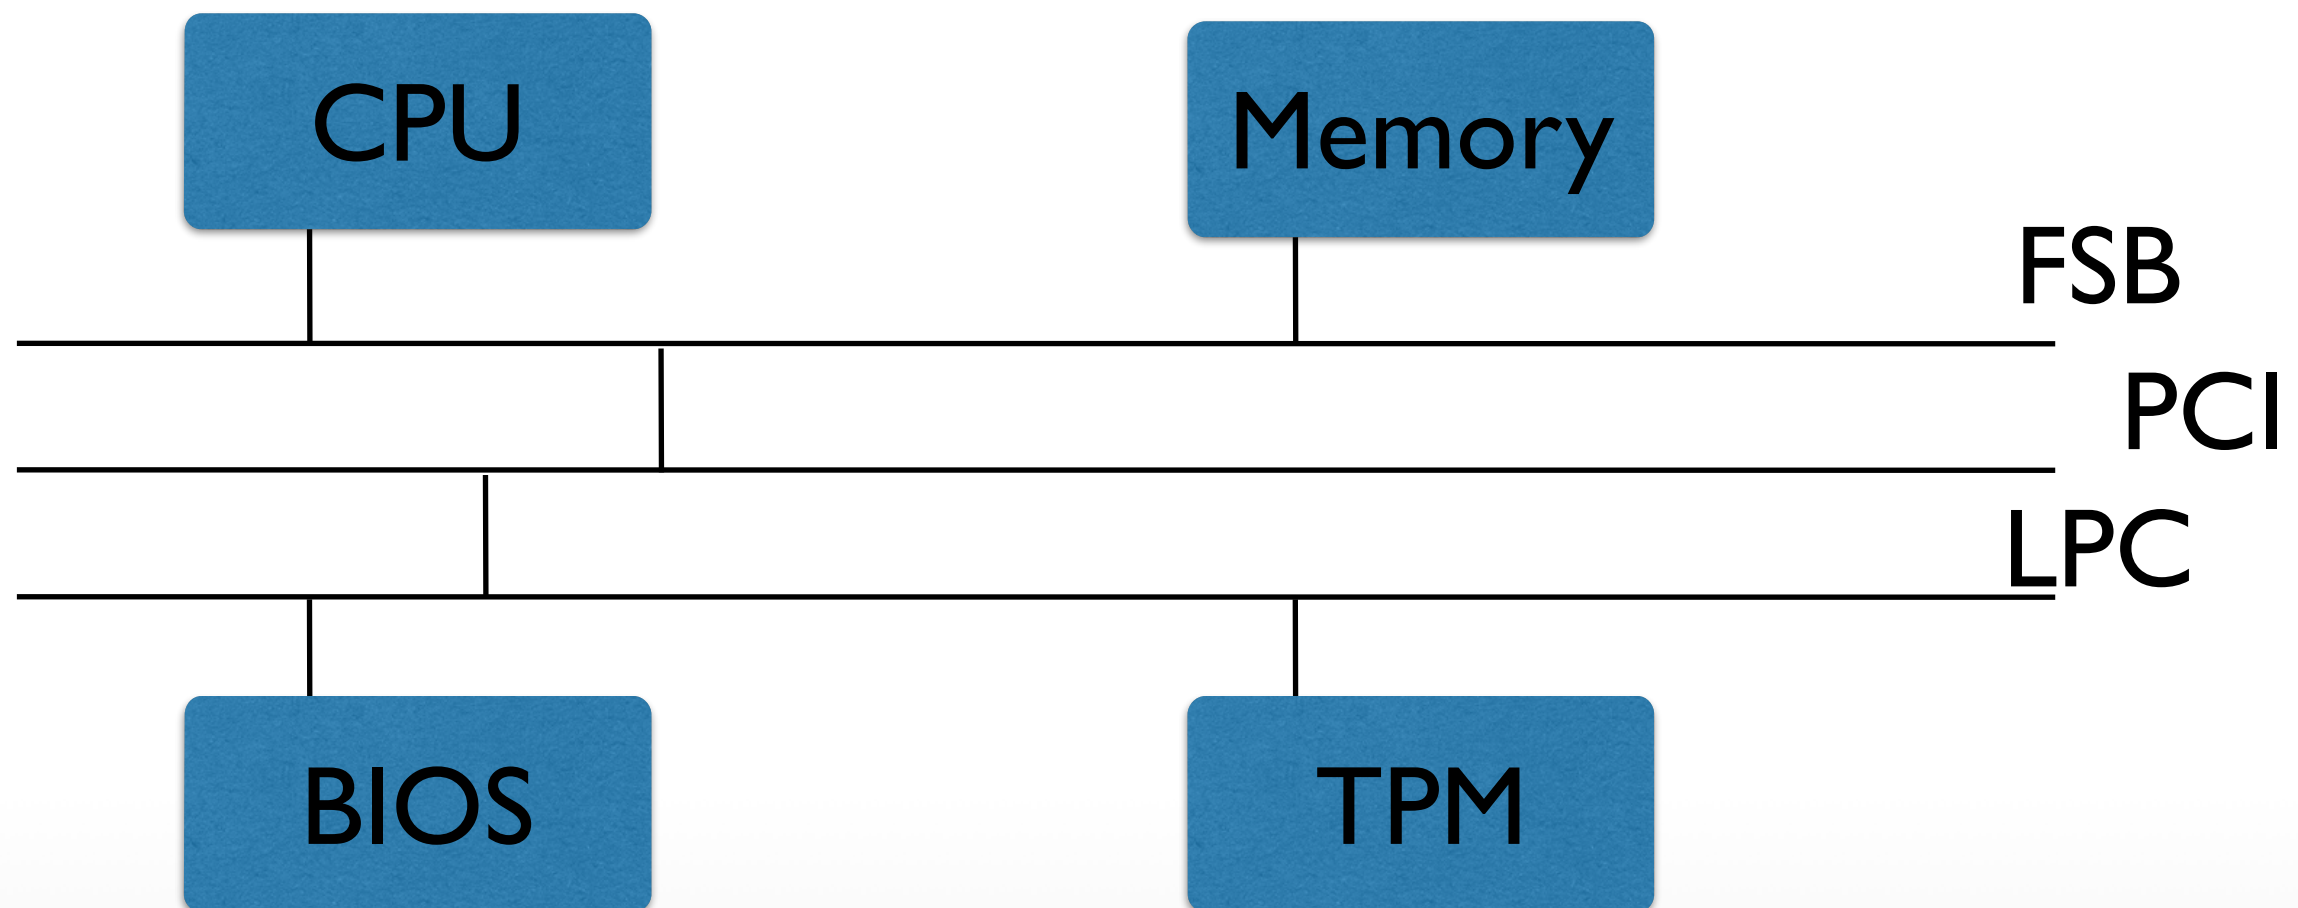

"seals" information such that it can be
unsealed by a future configuration
(for example: future OS version)

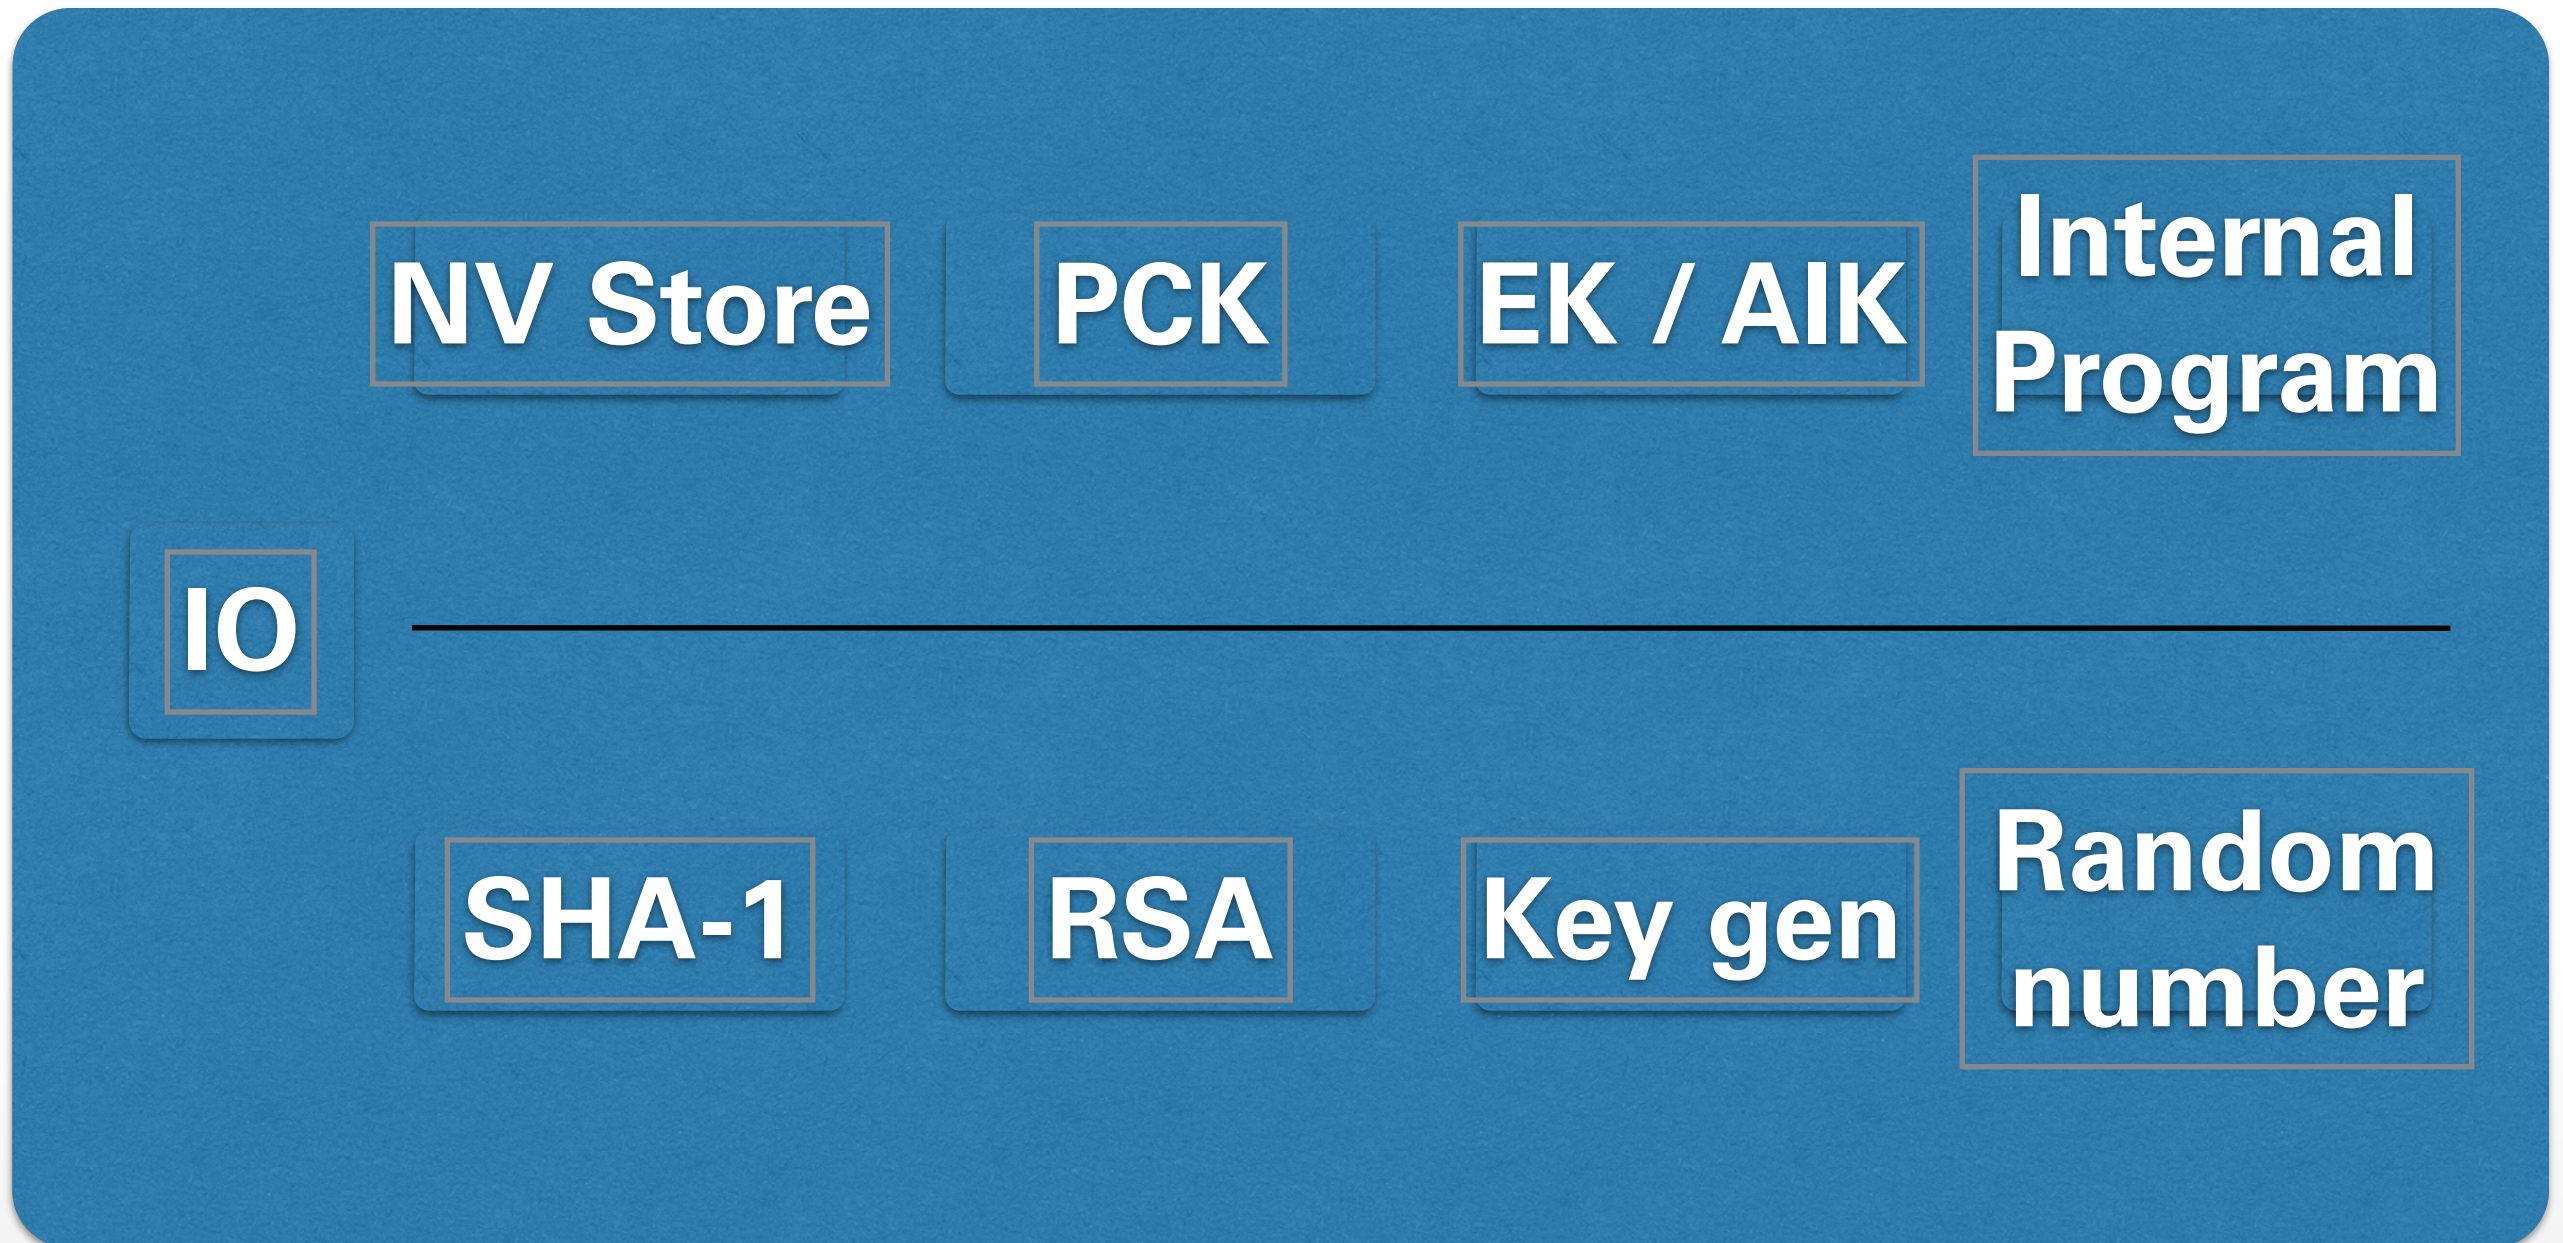

- Win8: Seal („SonyOS, Sony-Secret“)
→ SealedMessage (store it on disk)
- L4: Unseal (SealedMessage)
→ SonyOS, Sony-Secret
→ PCR#SonyOS
→ abort
- SonyOS: Unseal(SealedMessage
→ SonyOS, Sony-Secret
→ PCR==SonyOS
→ emit SonySecret

Ideally, includes CPU, Memory, ...

Current practice

- Additional physical protection, for example IBM 4758 ...
look it up in Wikipedia
- HW versions
 - TPM:
separate "Trusted Platform Modules"
(replacing BIOS breaks TRB)
 - Add a new privilege mode: ARM TrustZone
 - raise to user: Intel SGX
