

**TECHNISCHE  
UNIVERSITÄT  
DRESDEN**

**Faculty of Computer Science** Institute of Systems Architecture, Operating Systems Group

**“TRUSTED” COMPUTING**

**DISTRIBUTED OPERATING SYSTEMS**

**HERMANN HÄRTIG, SUMMER 2019**

Understand principles of:

- Authenticated booting, relation to (closed) secure booting
- Remote attestation
- Sealed memory
- Dynamic root of trust, late launch
- Protection of applications from the OS
- Point to implementation variants (TPM, iSGX, ARM-TZ)

Non-Goal:

- Lots of TPM, TCG, Trustzone, SGX details  
→ read the documents once needed

- Secure Booting
- Authenticated Booting
- (Remote) Attestation
- Sealed Memory
- Late Launch / dynamic root of trust
- Trusted Computing (Group) / Trusted Computing Base
  
- Beware of terminology chaos !

## Trusted Computing Base (TCB)

- The set off all components, *hardware, software, procedures*, that must be relied upon to enforce a security policy.

## Trusted Computing (TC)

- A particular technology comprised of authenticated booting, remote attestation and sealed memory.

- Can running certain Software be prevented?
- Which computer system do I communicate with ?
- Which stack of Software is running?
  - In front of me?
  - On my server somewhere?
- Restrict access to certain secrets (keys) to certain software?
- Protect an application against the OS

## Digital Rights Management:

- Provider sells content
- Provider creates key, encrypts content
- Client downloads encrypted content, stores on disk
- Provider sends key, but needs to ensure that only specific SW can use it
- Has to work also when client is off line
- PROVIDER DOES NOT TRUST CUSTOMER

## **Virtual machine provided by cloud**

- Client buys Cycles + Storage (Virtual machine)
- Client provides its own operating system
- Needs to ensure that provided OS runs
- Needs to ensure that provider cannot access data
- CUSTOMER DOES NOT TRUST PROVIDER

## **Industrial Plant Control (Uranium enrichment)**

- Remote Operator sends commands, keys
- Local operator occasionally has to run test SW, update to new version, ...
- Local technicians are not Trusted

## **Anonymity Service**

- Intended to provide anonymous communication over internet
- Legal system can request introduction of trap door (program change)
- Anonymity-service provider not trusted

## Measuring

- “process of obtaining metrics of platform characteristics”
- example for metric: Hash- Codes of SW

## Attestation

- “vouching for accuracy of information”

## Sealed Memory

- binding information to a configuration

- $H(M)$   
Collision-Resistant Hash Function  $H$   
applied to content  $M$
- $S_{\text{pair}}$ :  $S_{\text{priv}}$   $S_{\text{pub}}$   
Asymmetric key pair of entity  $S$   
used to conceal or sign some content  
 $S_{\text{pub}}$  is published,  $S_{\text{priv}}$  must be kept secret
- $S_{\text{symm}}$   
symmetric key, must be kept secret ("secret key")

- “Digital Signature”:  $\{ M \} S^{\text{priv}}$ 
  - $S^{\text{pub}}$  can be used to verify that S has signed M
  - is short for:  $( M, \text{encrypt}(H(M), S^{\text{priv}}) )$
  - $S^{\text{pub}}$  is needed and sufficient to check signature
- “Concealed Message”:  $\{ M \} S^{\text{pub}}$ 
  - Message concealed for S
  - $S^{\text{priv}}$  is needed to unconceal M

Program vendor: Foosoft FS

Two ways to identify Software: Hash / Public Key

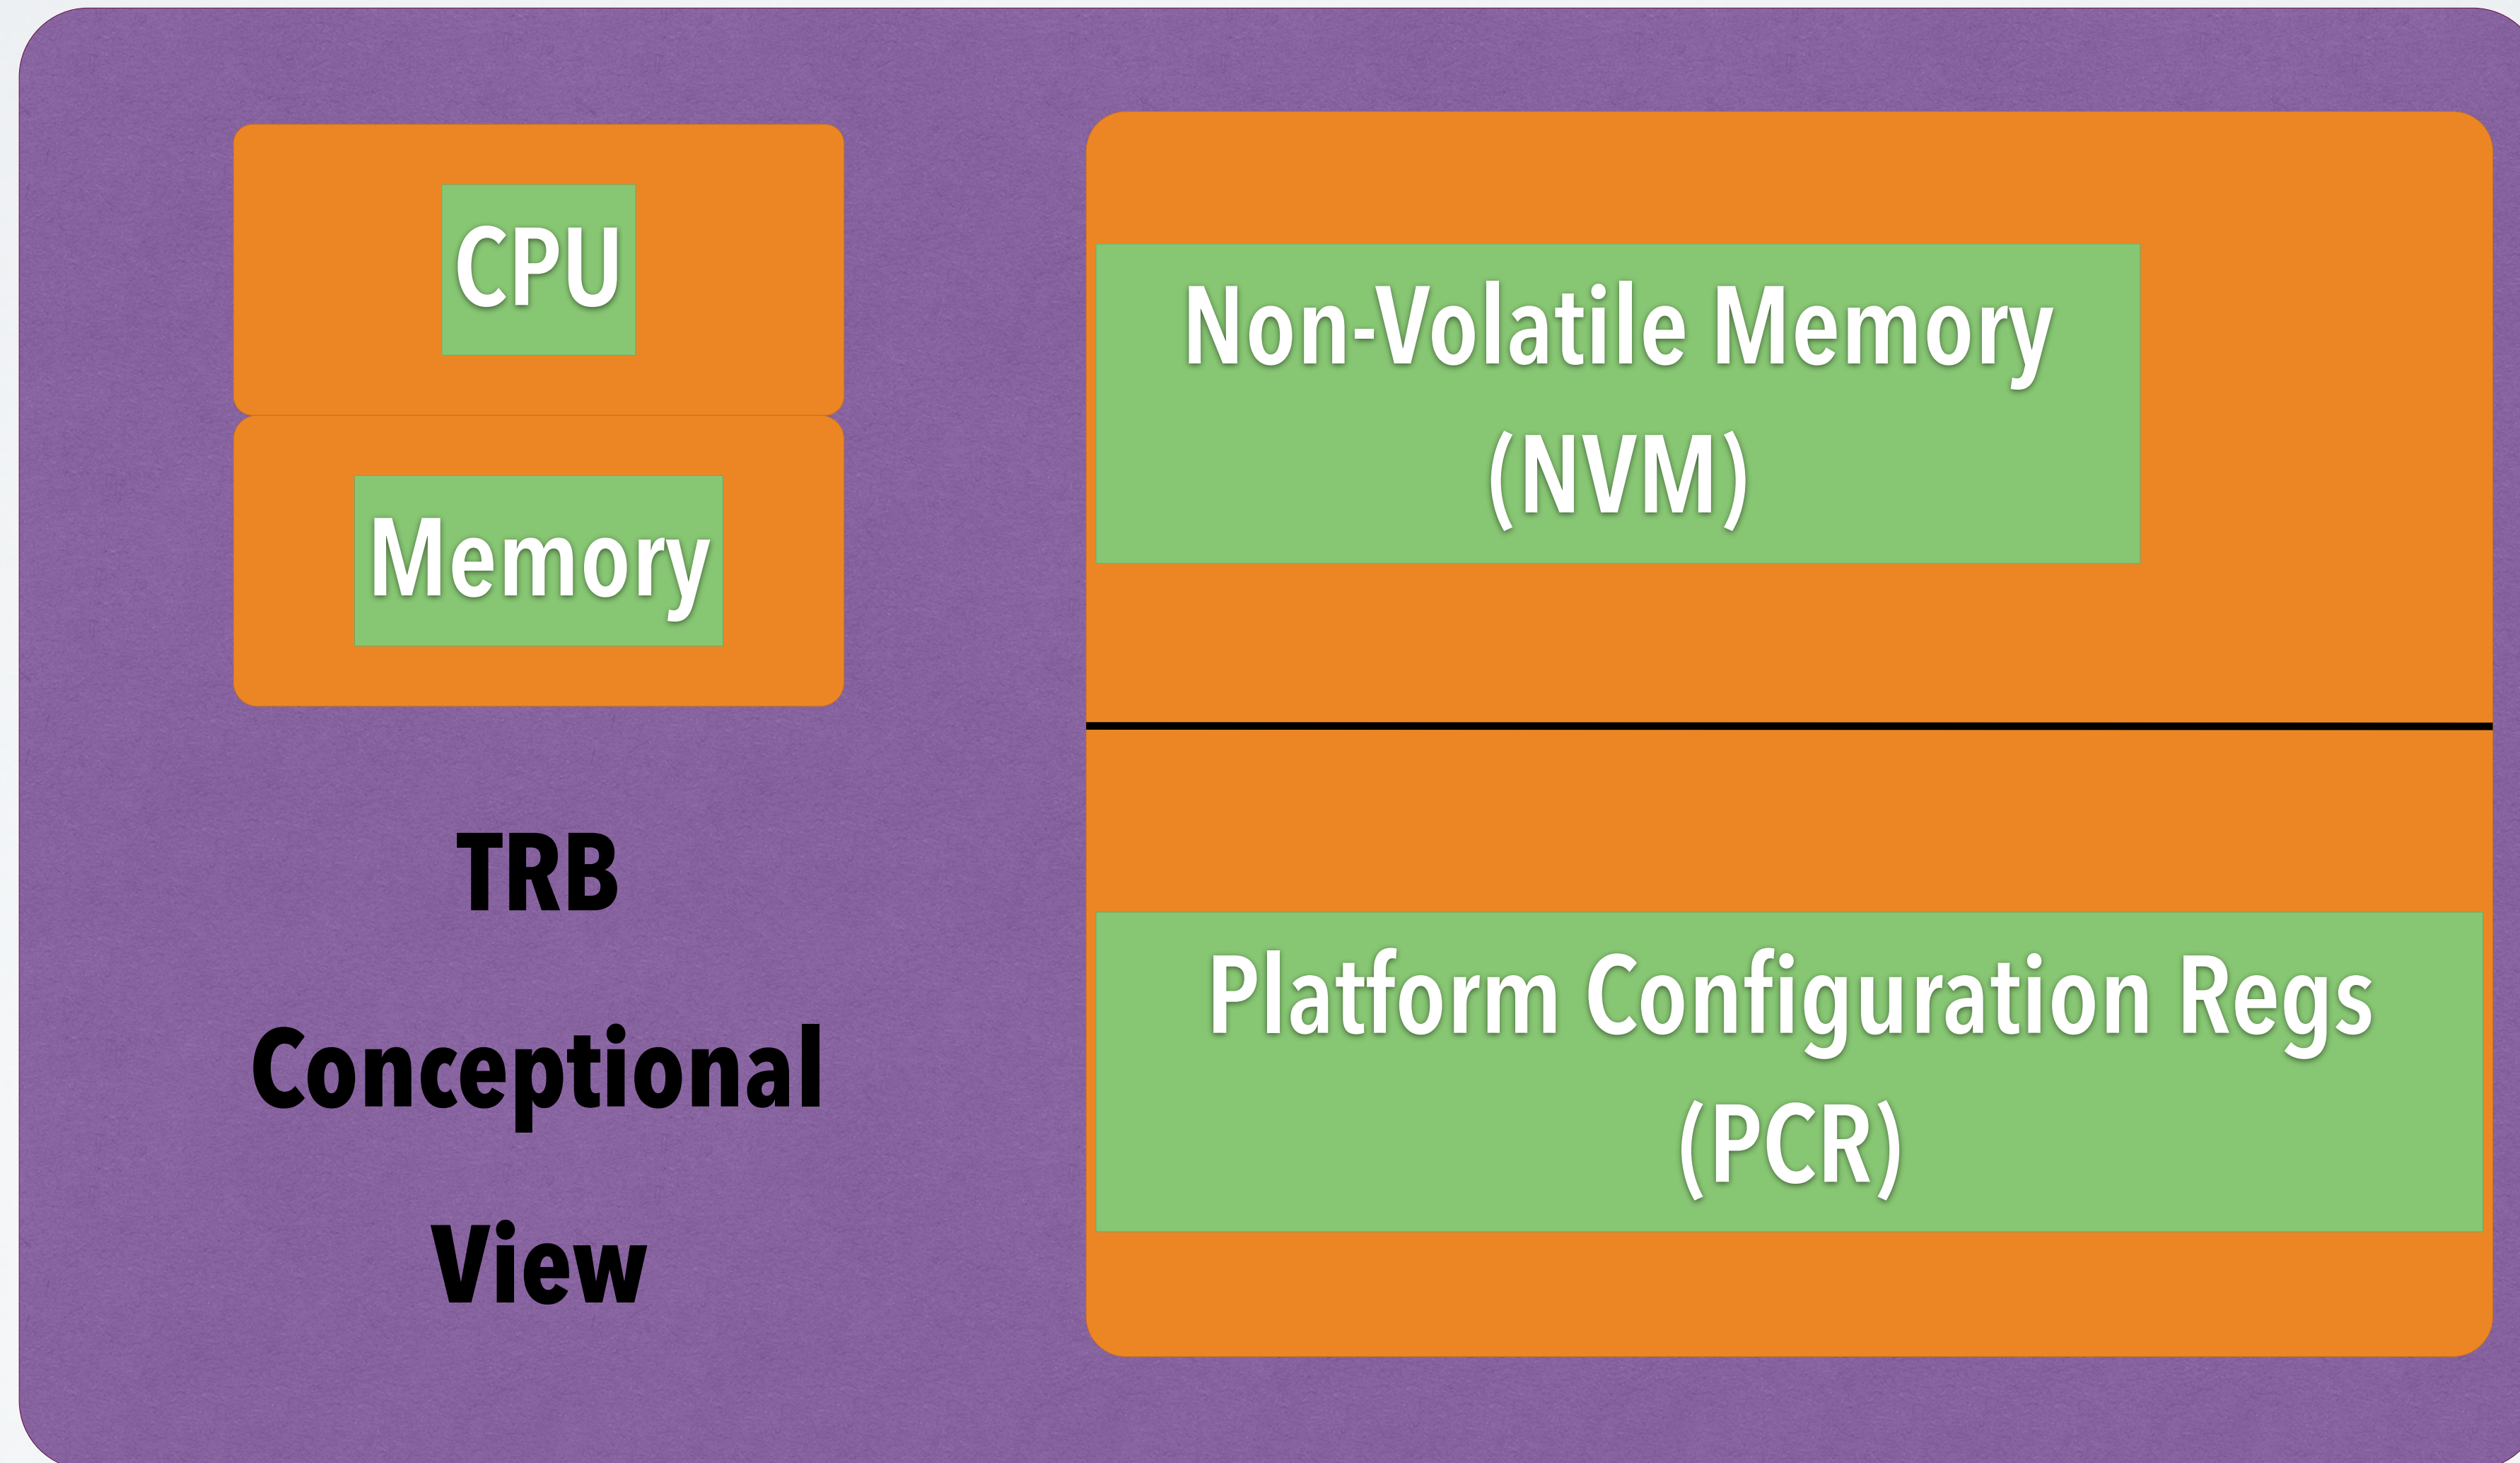

- $H(\text{Program})$
- $\{\text{Program}, \text{ID- Program}\}_{\text{FS}^{\text{priv}}}$   
use  $\text{FS}^{\text{pub}}$  to check  
the signature must be made available,  
e.g. shipped with the Program

The „ID“ of SW must be known.

$H(\text{Program})$  and  $\text{FS}^{\text{pub}}$  can serve as ID.

# Tamperresistant Black Box(TRB)

- Read-Only Memory (Flash)
- H(OS) in NVM preset by manufacturer
  - load OS- Code
  - compare H(loaded OS code) to preset H(OS)
  - abort if different
- $FS_{pub}$  in NVM preset by manufacturer
  - load OS- Code
  - check signature of loaded OS-Code using  $FS_{pub}$
  - abort if check fails

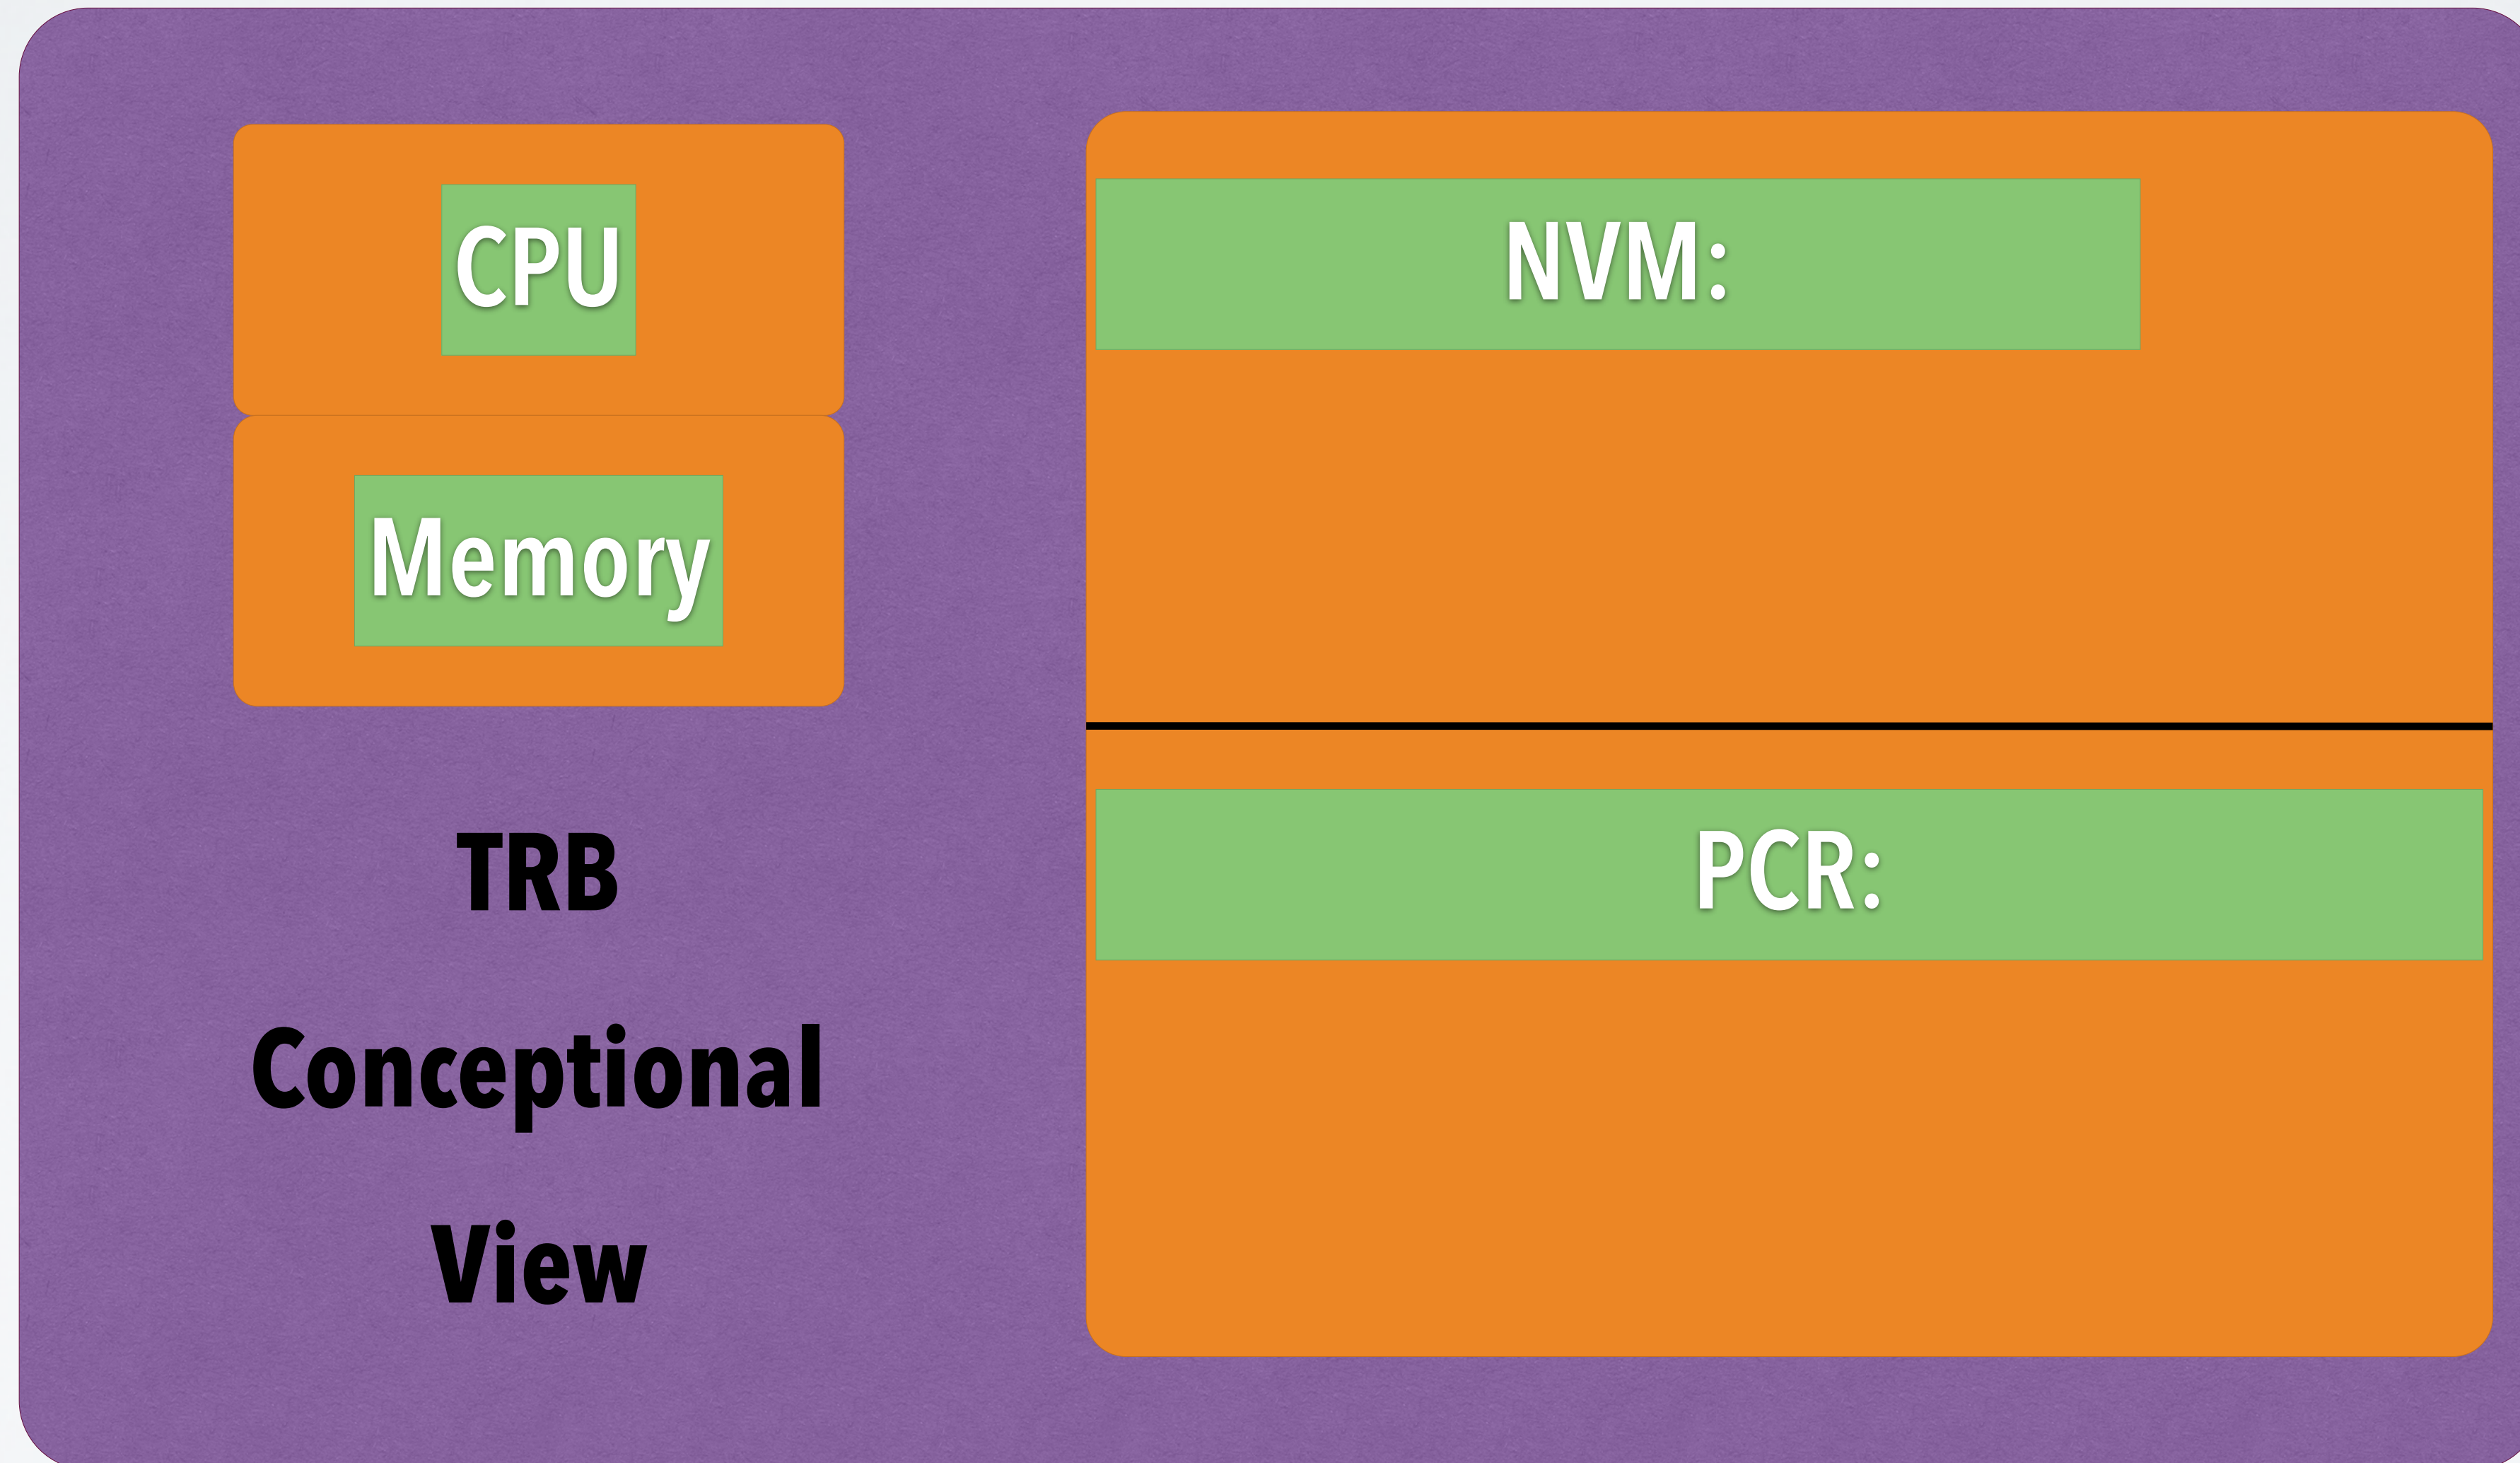

Steps:

- A. Preparation by TRB and OS Vendors
- B. Booting & "Measuring"
- C. Remote attestation

# Tamperresistant Black Box(TRB)

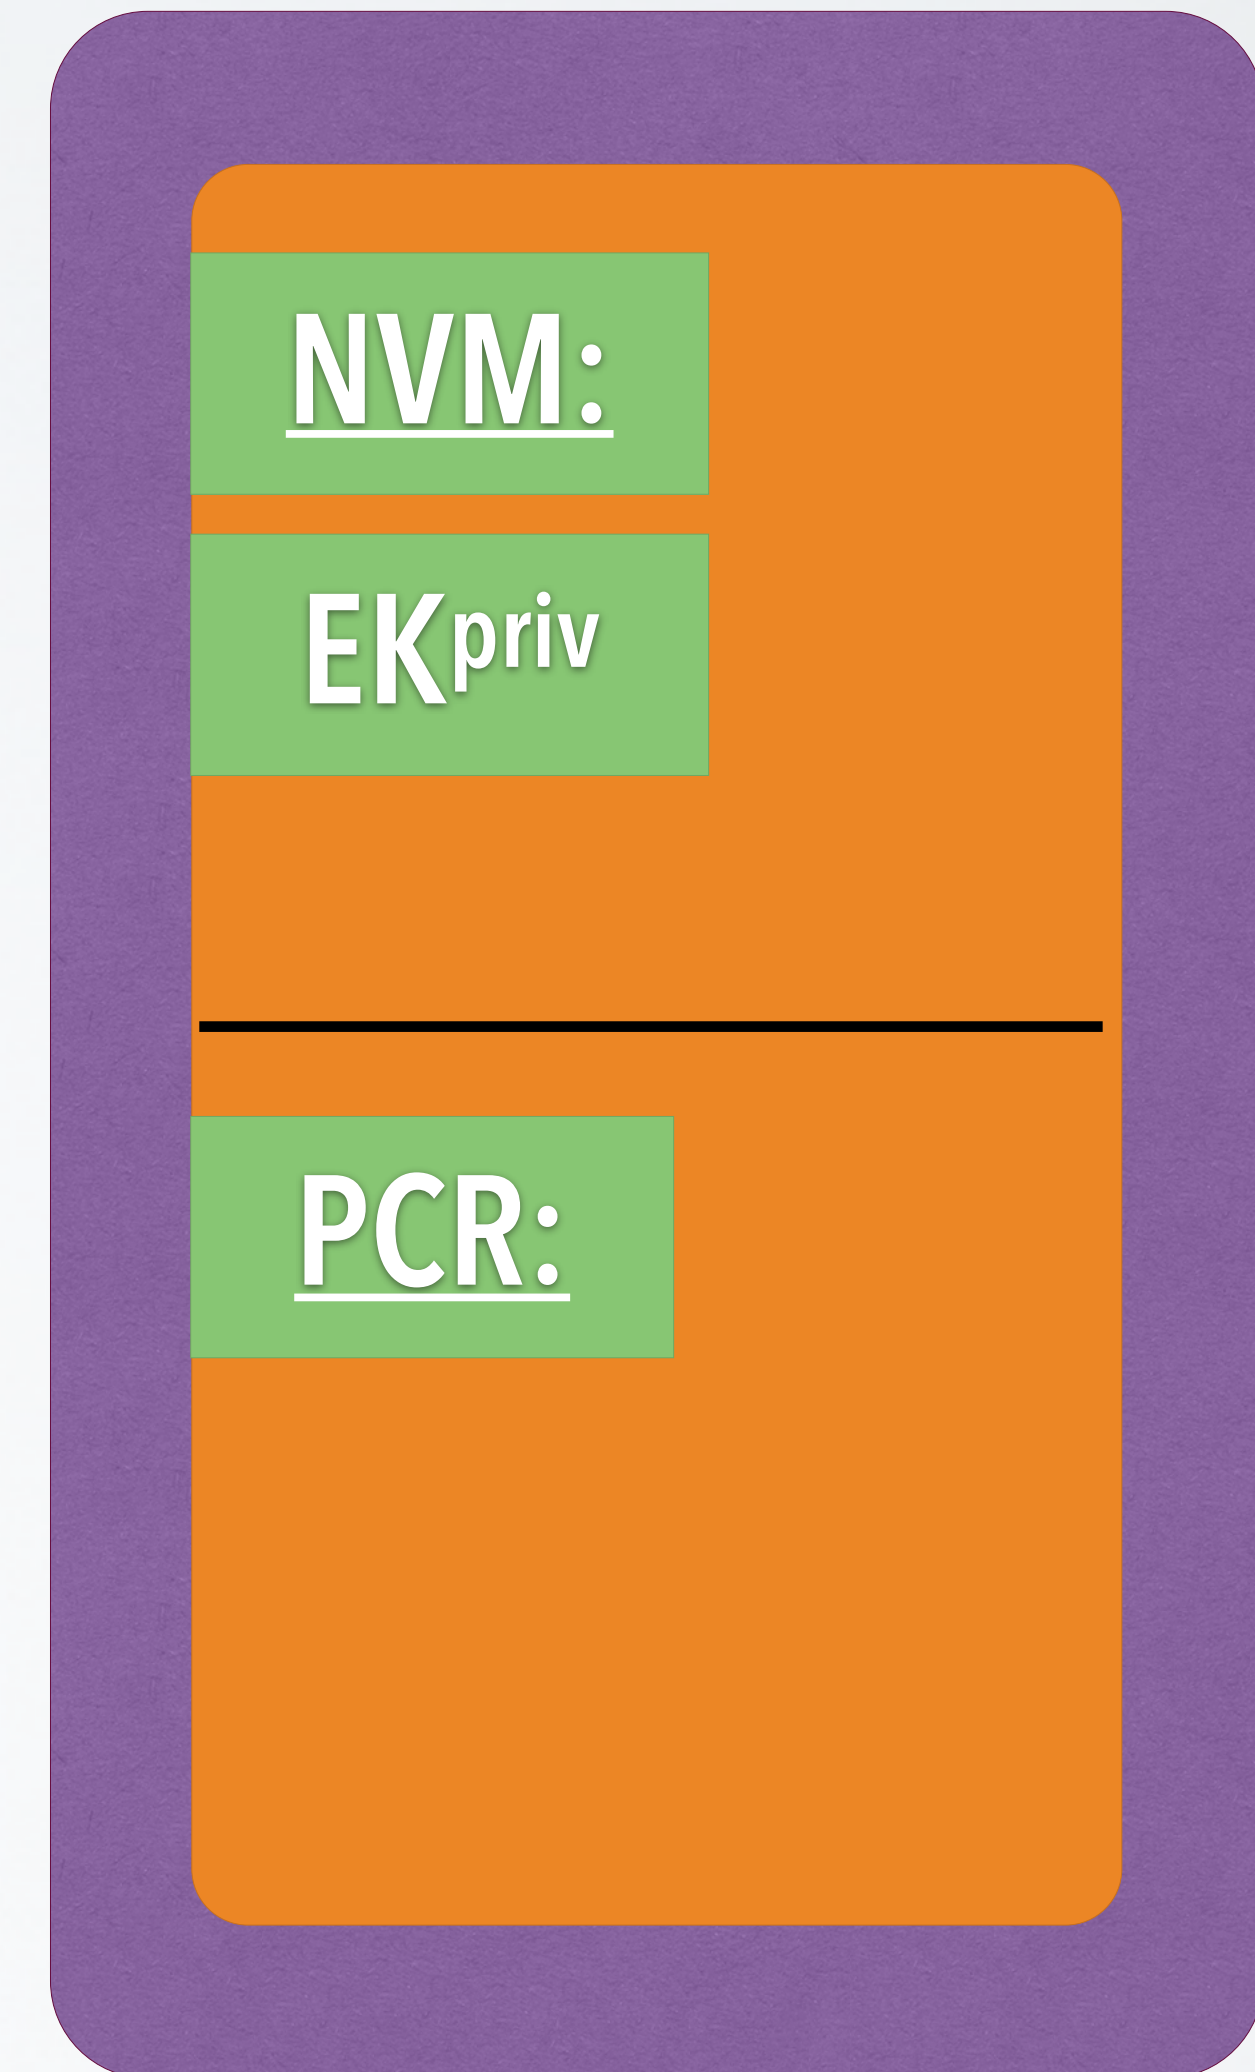

# Tamperresistant Black Box(TRB)

TRB generates key pair:  
„Endorsement Key“  $EK_{\text{pair}}$   
stores  $EK_{\text{priv}}$  in TRB NVM  
publishes  $EK_{\text{pub}}$

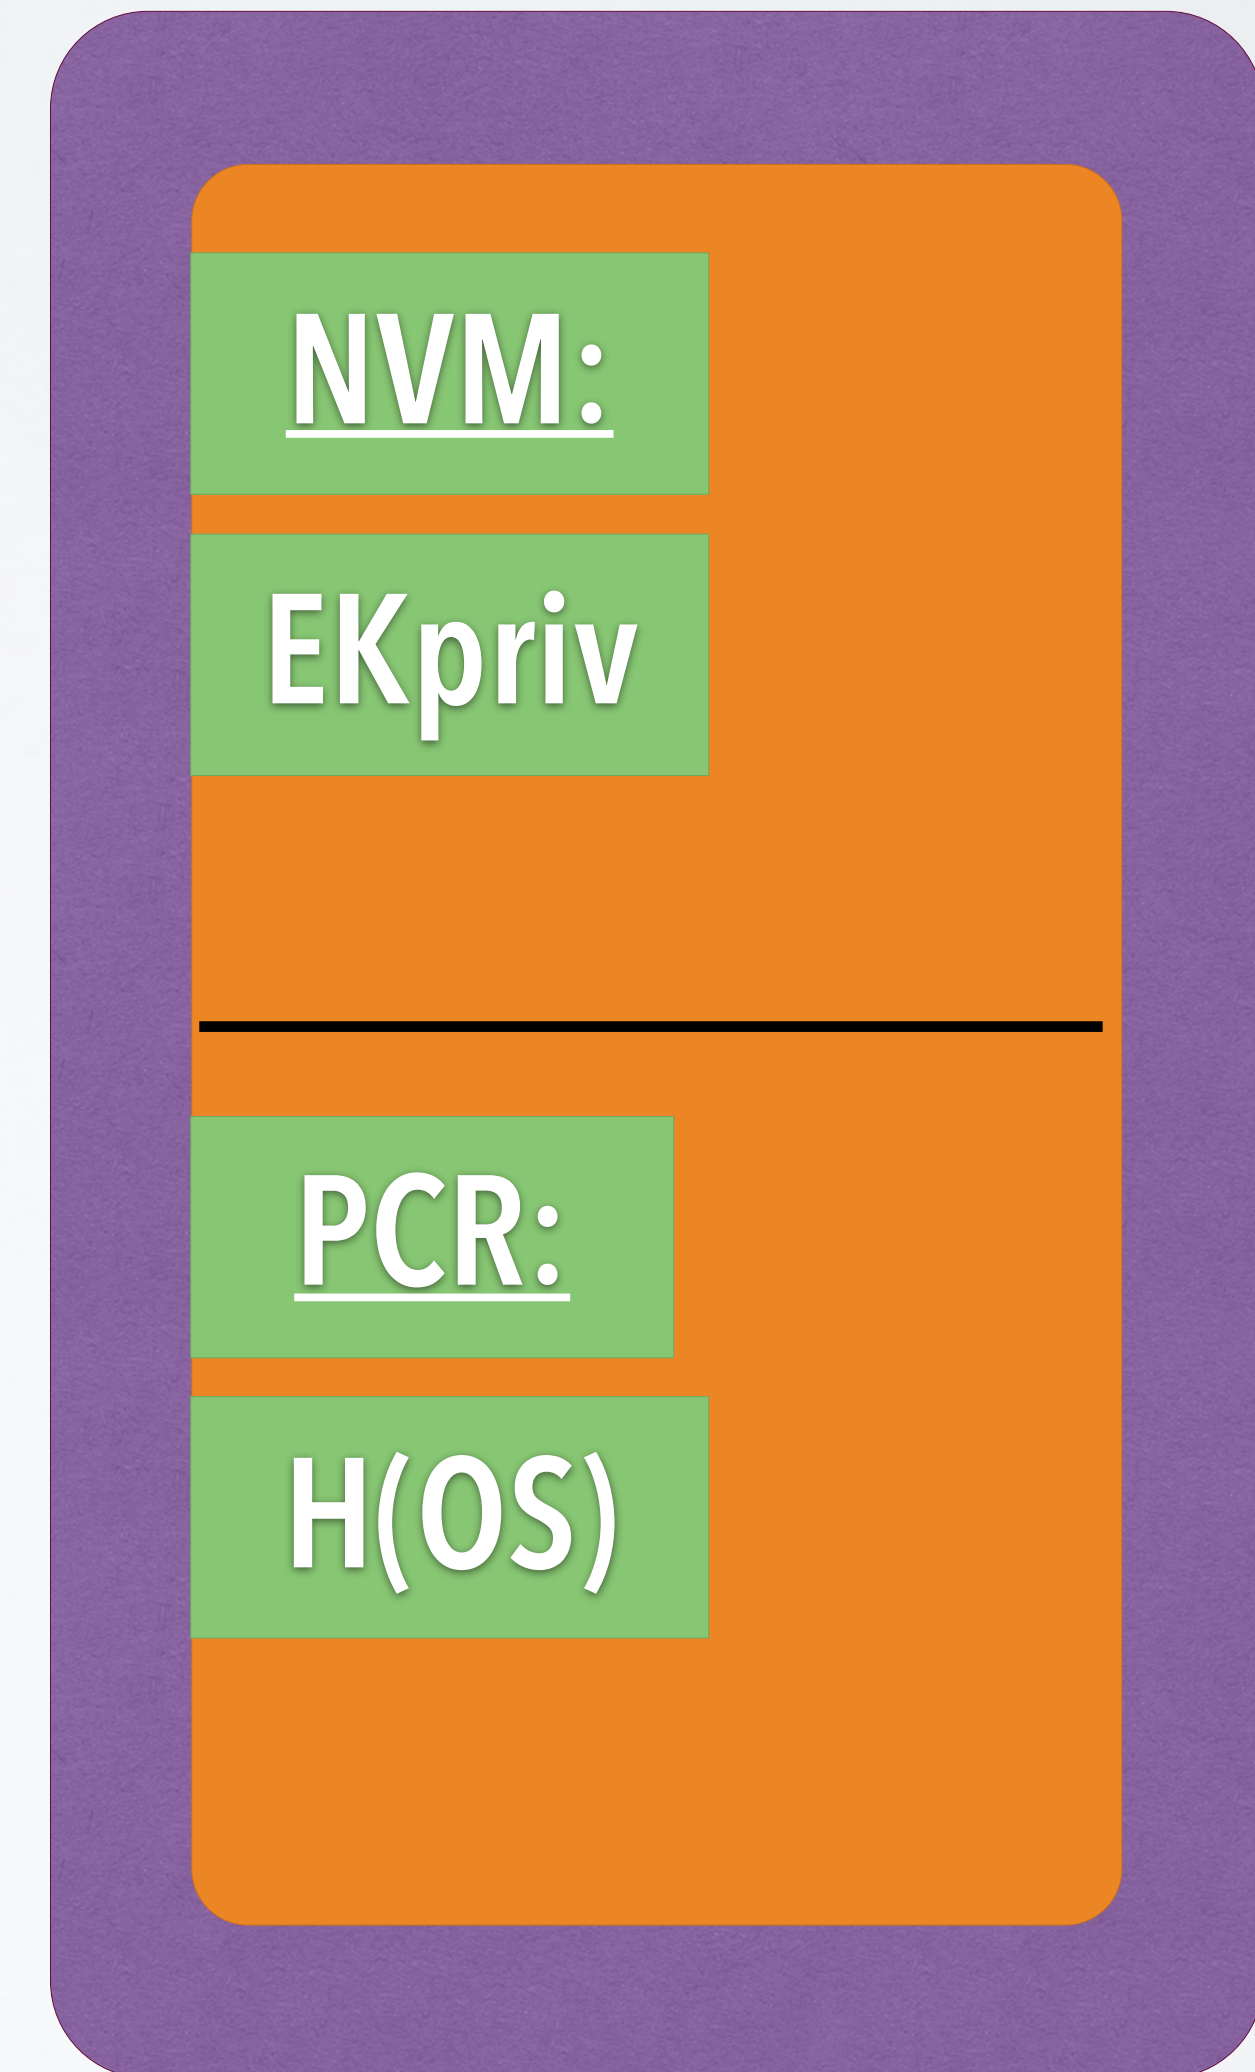

- TRB vendor certifies:  
 $\{\text{"a valid EK"}, EK_{\text{pub}}\} \text{TRB\_Vendor}_{\text{priv}}$
- OS-Vendor certifies:  
 $\{\text{"a valid OS"}, H(\text{OS})\} \text{OS\_Vendor}_{\text{priv}}$
- serve as identifiers:  
 $EK_{\text{pub}}$  and  $H(\text{OS})$

TRB:

- resets TRB !
- measures OS code  $H(OS)$
- stores  $H(OS)$  in PCR

PCR not (directly) writable by OS

more later

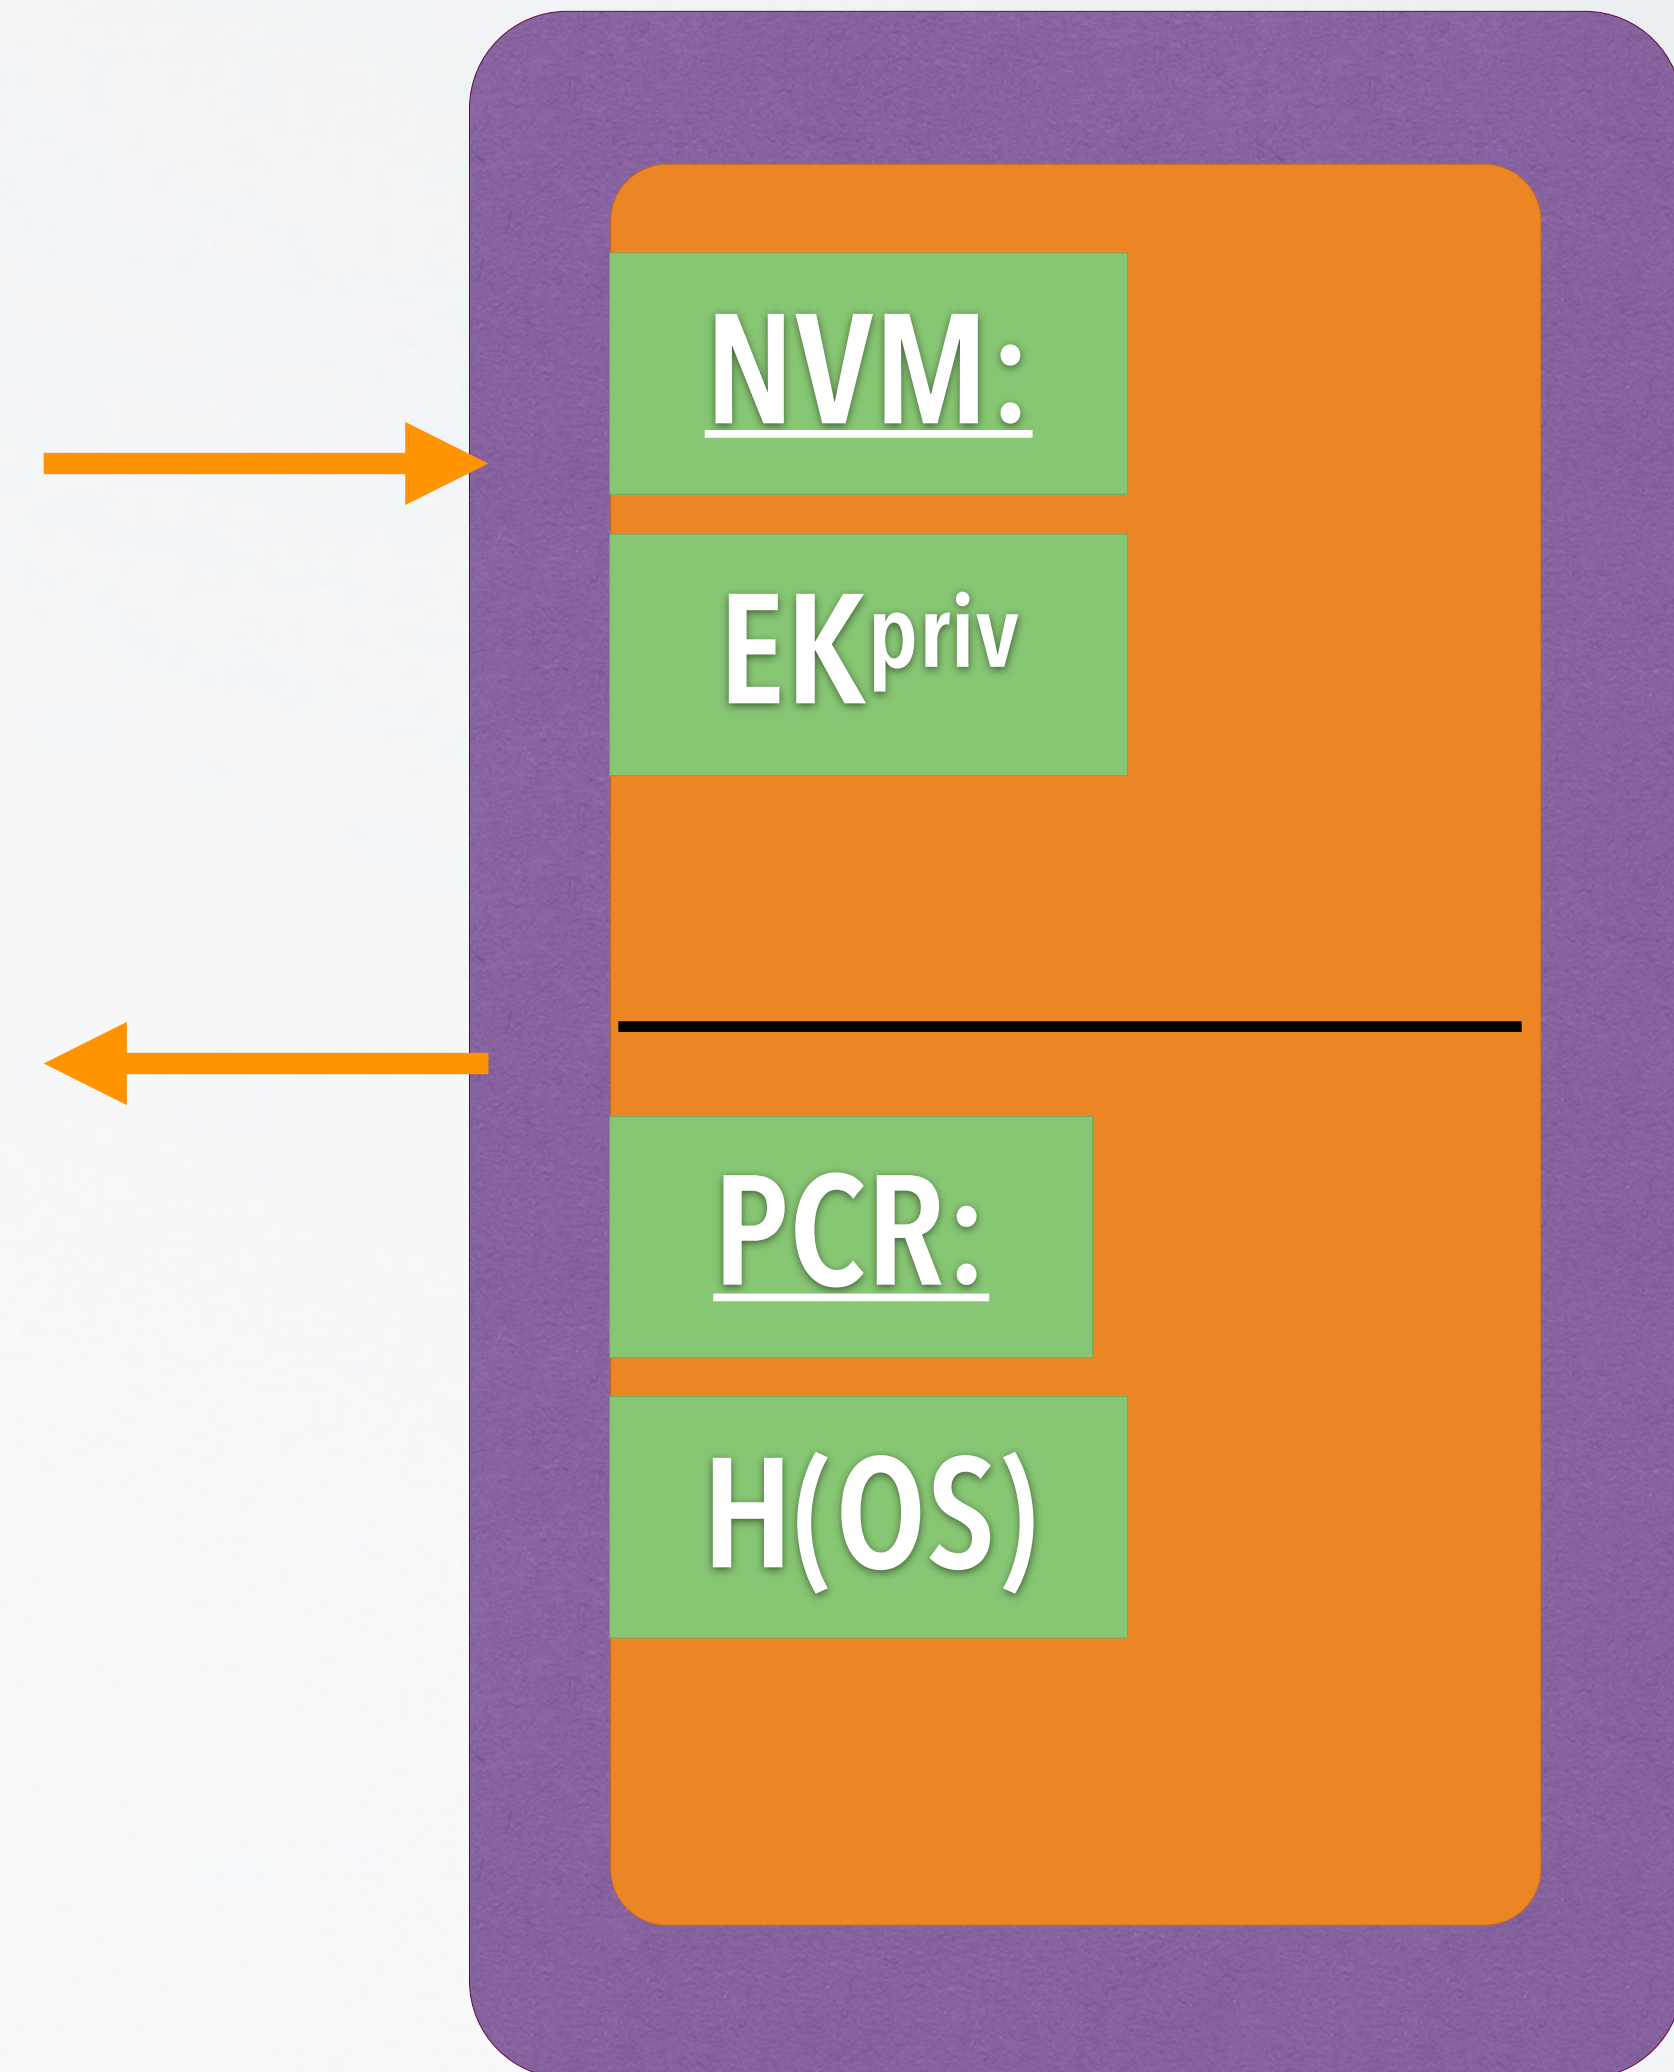

Challenge:

send NONCE

Response:

$\{\text{NONCE}', \text{PCR}\}_{\text{EK}_{\text{priv}}}$

- boot Linux
  - challenge
  - ← response "Linux"
- reboot Windows
  - send data

add one step of indirection:

create keypairs at each reboot

At booting, TRB :

- computes  $H(OS)$  and stores in PCR
- creates 2 keypairs for the booted, "active" OS (like "Session key"):
  - $ActiveOSAuth_{pair}$  /\* for Authentication
  - $ActiveOSCons_{pair}$  /\* for Concellation
- certifies:  
 $\{ ActiveOSAuthK_{pub}, ActiveOSConsK_{pub}, H(OS) \} EK_{priv}$
- hands over  $ActiveOSKeys$  to booted OS

## Remote Attestation:

- Challenge: nonce

- Active OS generates response:

$\{ \text{ActiveOSCons}^{\text{pub}}, \text{ActiveOSAuth}^{\text{pub}}, H(\text{OS}) \} \text{EK}^{\text{priv}}$

/\* see previous slide

$\{ \text{nonce}' \} \text{ActiveOSAuth}^{\text{priv}}$

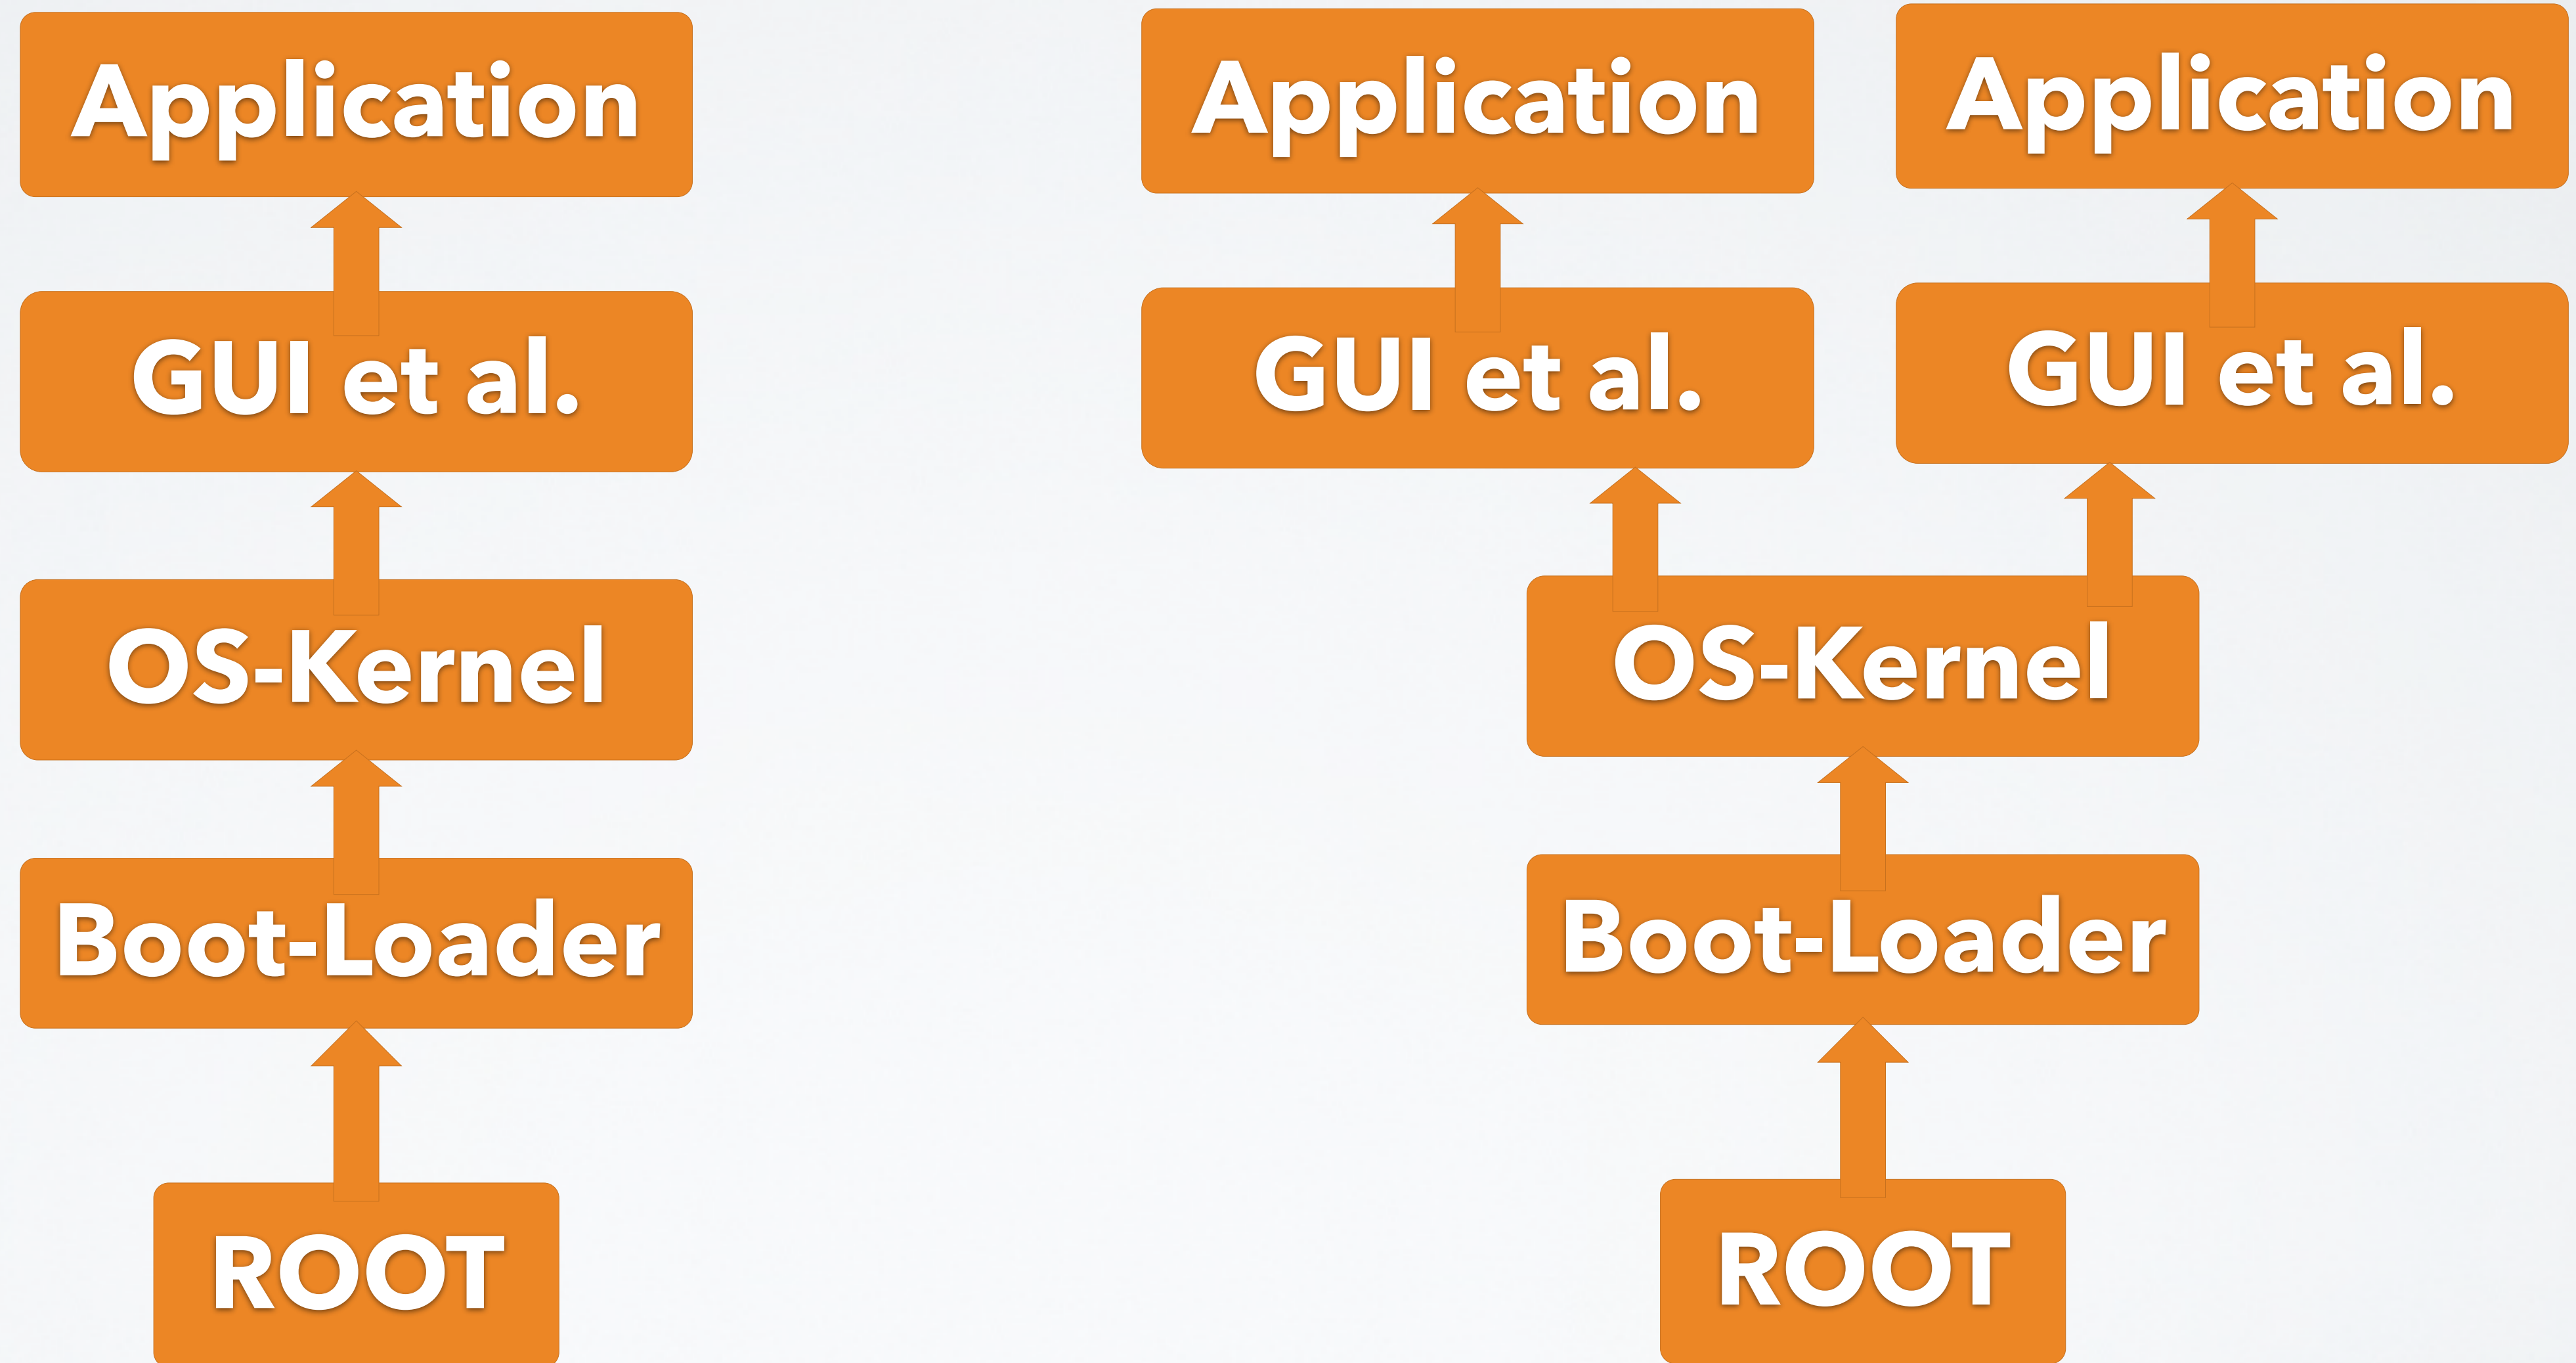

## Secure channel:

$\{ \text{message} \} \text{ActiveOSCons}^{\text{pub}}$

- TRB can protect:  $EK_{priv}$ , PCR  
OS can protect: "Active OS keys"
- Rebooting destroys content of
  - PCR
  - Memory Holding "Active OS keys"

# Software Stacks and Trees

## 2 Concerns:

- Very large Trusted Computing Base for Booting (including Device Drivers etc)
- Remote attestation of one process (leaf in tree)

“Extend” Operation:

- stack:  $PCR_n = H(PCR_{n-1} \parallel \text{next-component})$
- tree: difficult (“hearsay”: possible, unpublished ?)

Key pairs per step:

- OS controls applications → generate key pair per application
- OS certifies
  - { Application 1, App1Kpub } ActiveOSAuth<sub>priv</sub>
  - { Application 2, App2Kpub } ActiveOSAuth<sub>priv</sub>

Problem: huge Software to boot system !!!

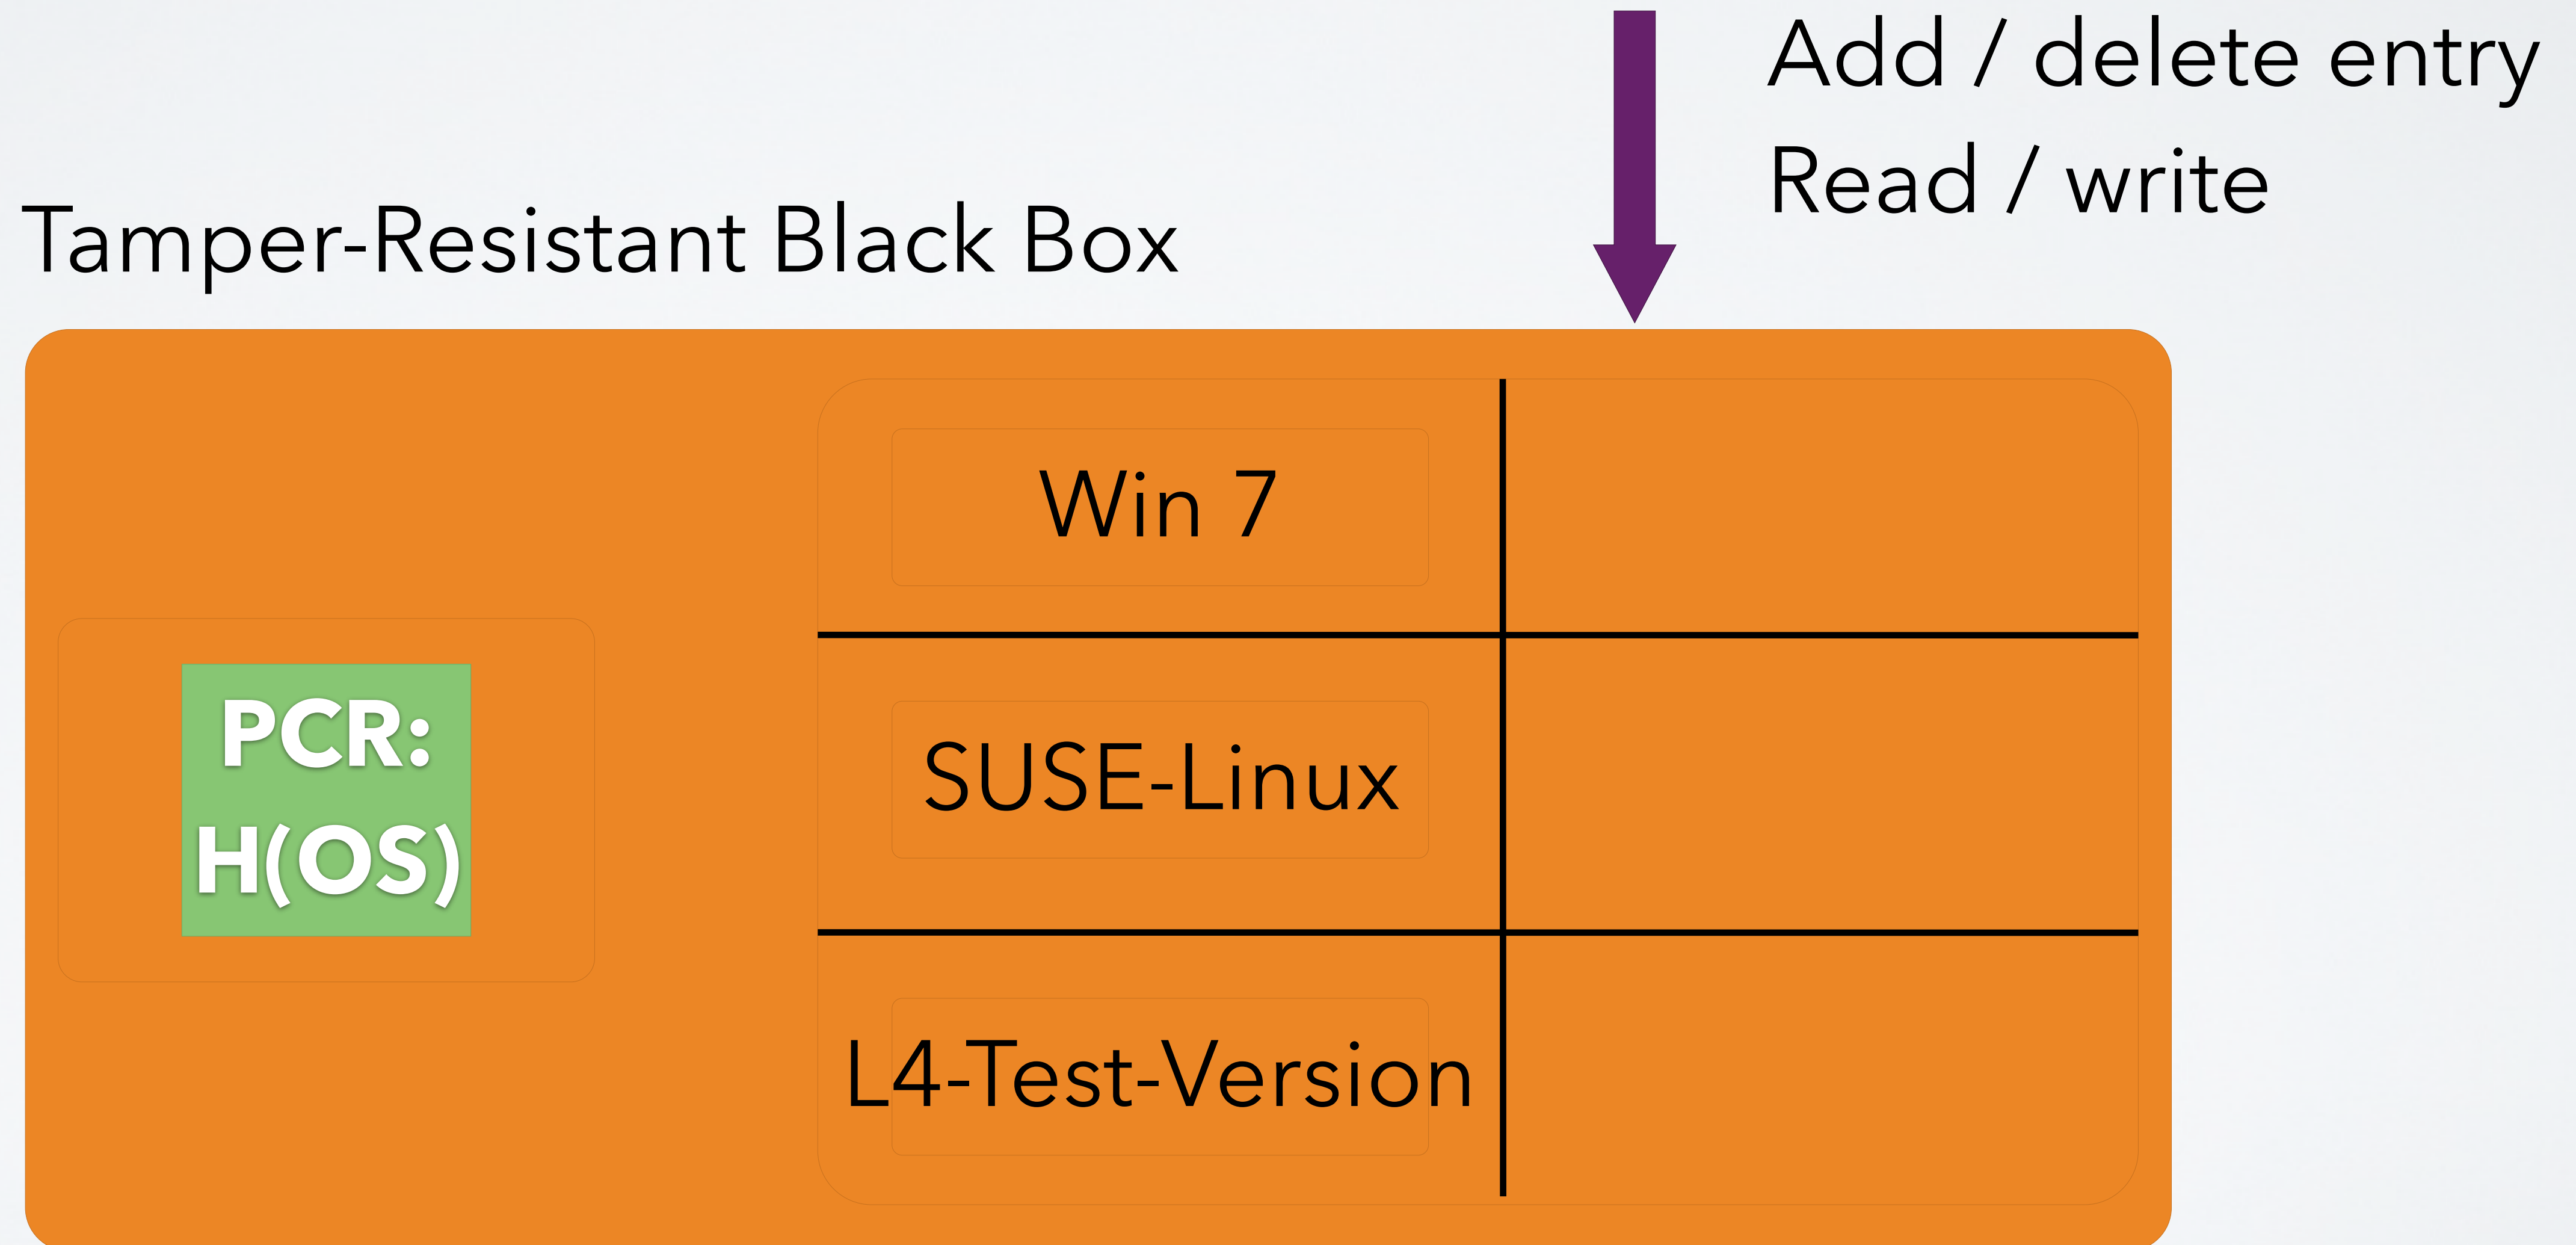

- Use arbitrary SW to start system and load all SW
- provide specific instruction to enter "secure mode"
  - set HW in specific state (stop all processors, IO, ...)
  - Measure "root of trust" SW and store in PCR
- AMD: "skinit" (Hash) arbitrary root of trust
- Intel: "senter" (must be signed by chip set manufacturer)

## Goal:

- Send information using secure channels
- Bind that information to Software configuration
- Work offline:  
How to store information in the absence of communication channels?
- For example DRM:  
bind encryption keys to specific machine, specific OS

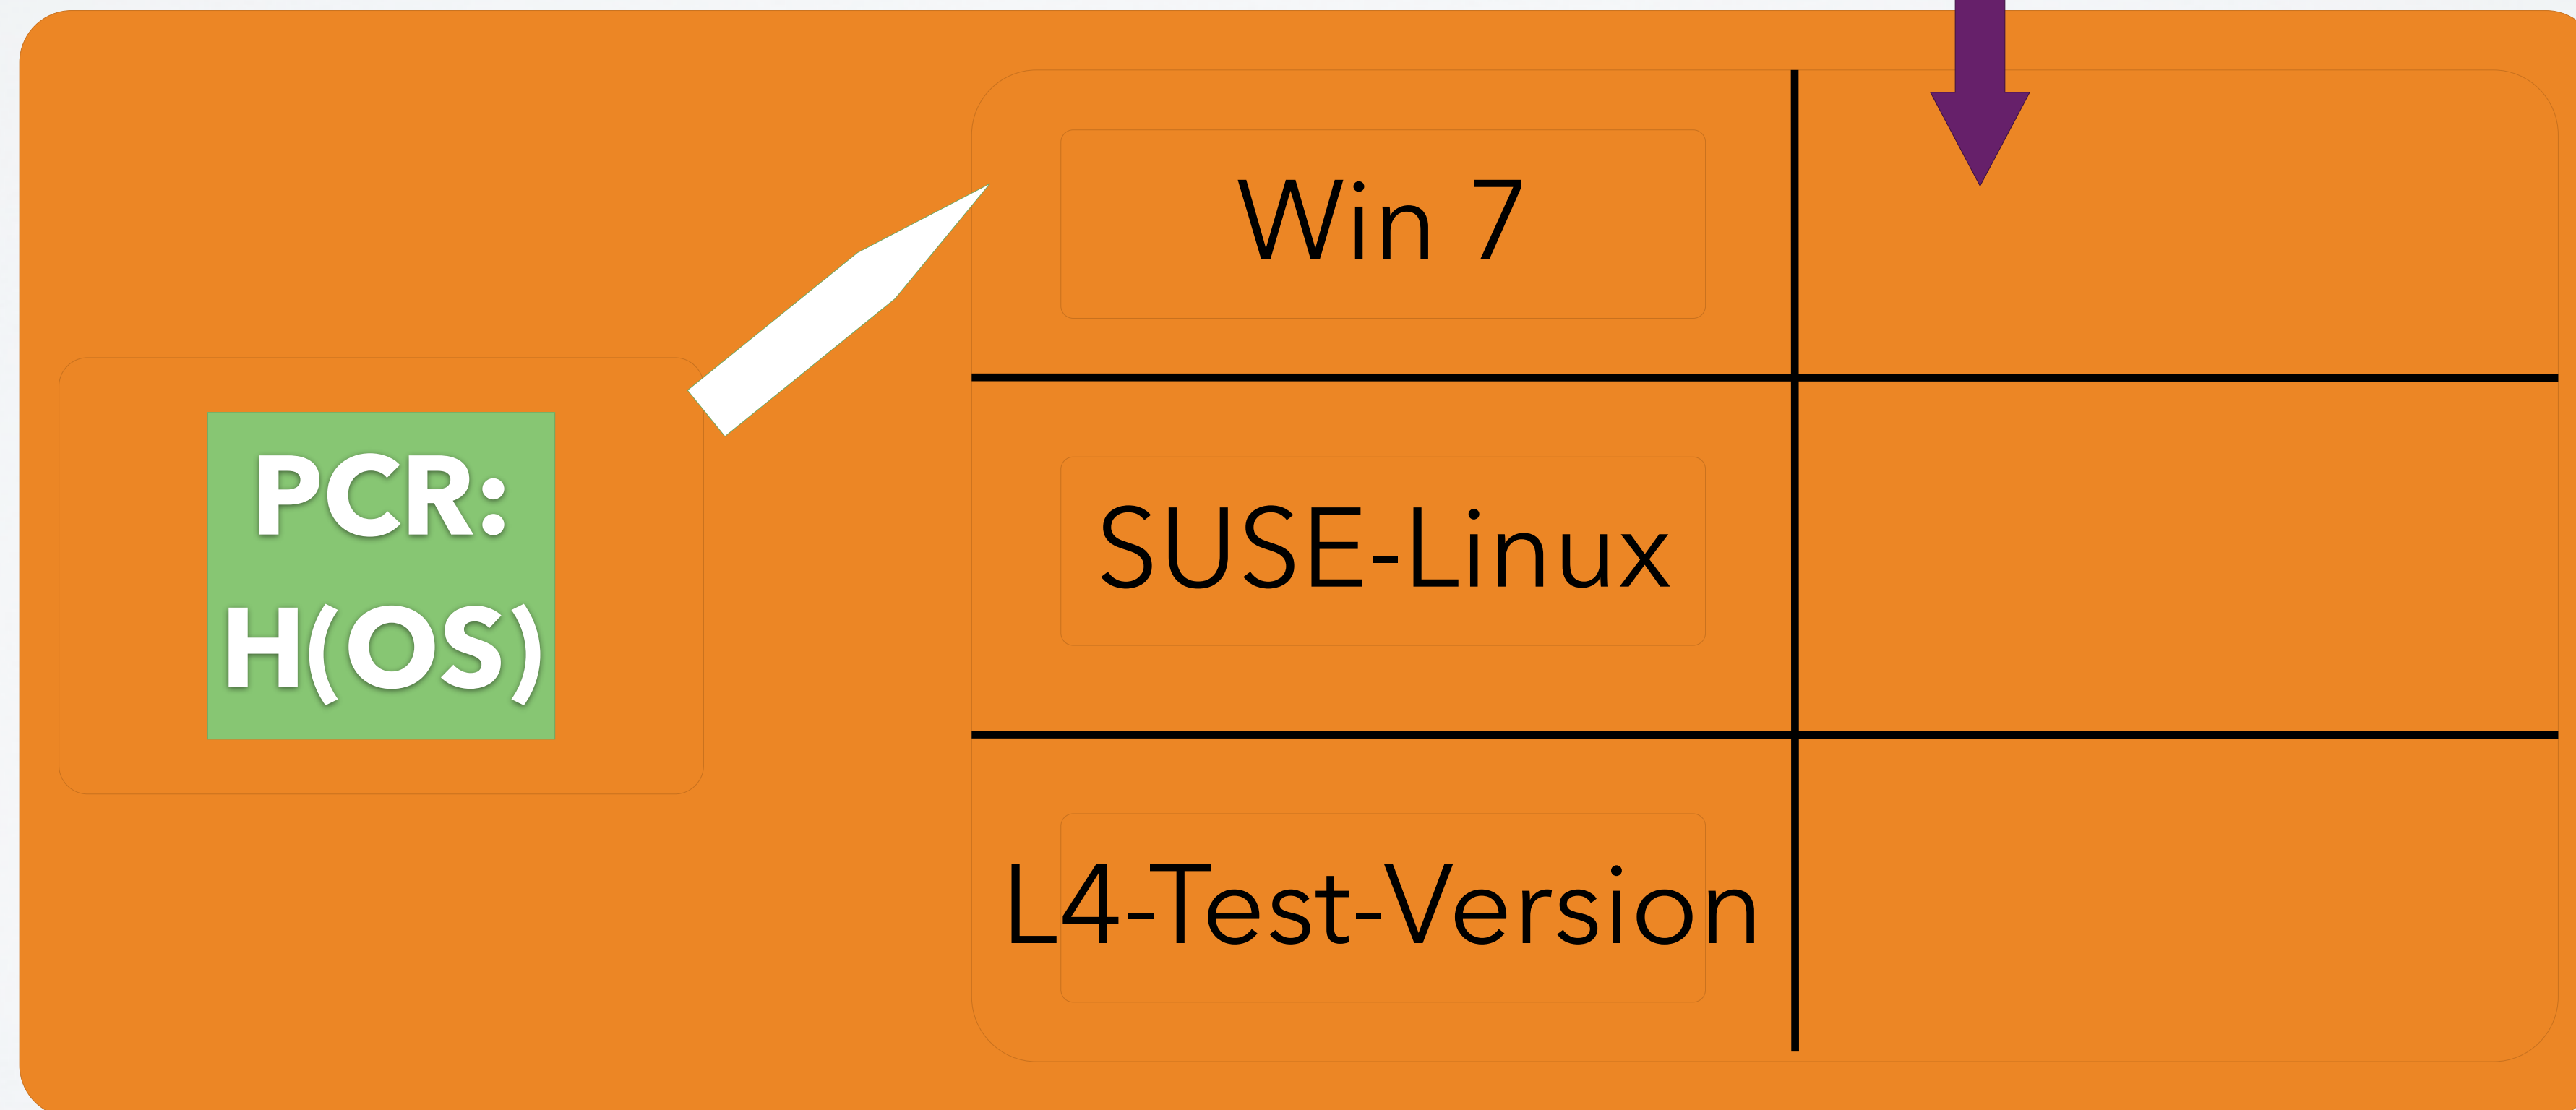

# Sealed Memory Principle

# Sealed Memory Principle

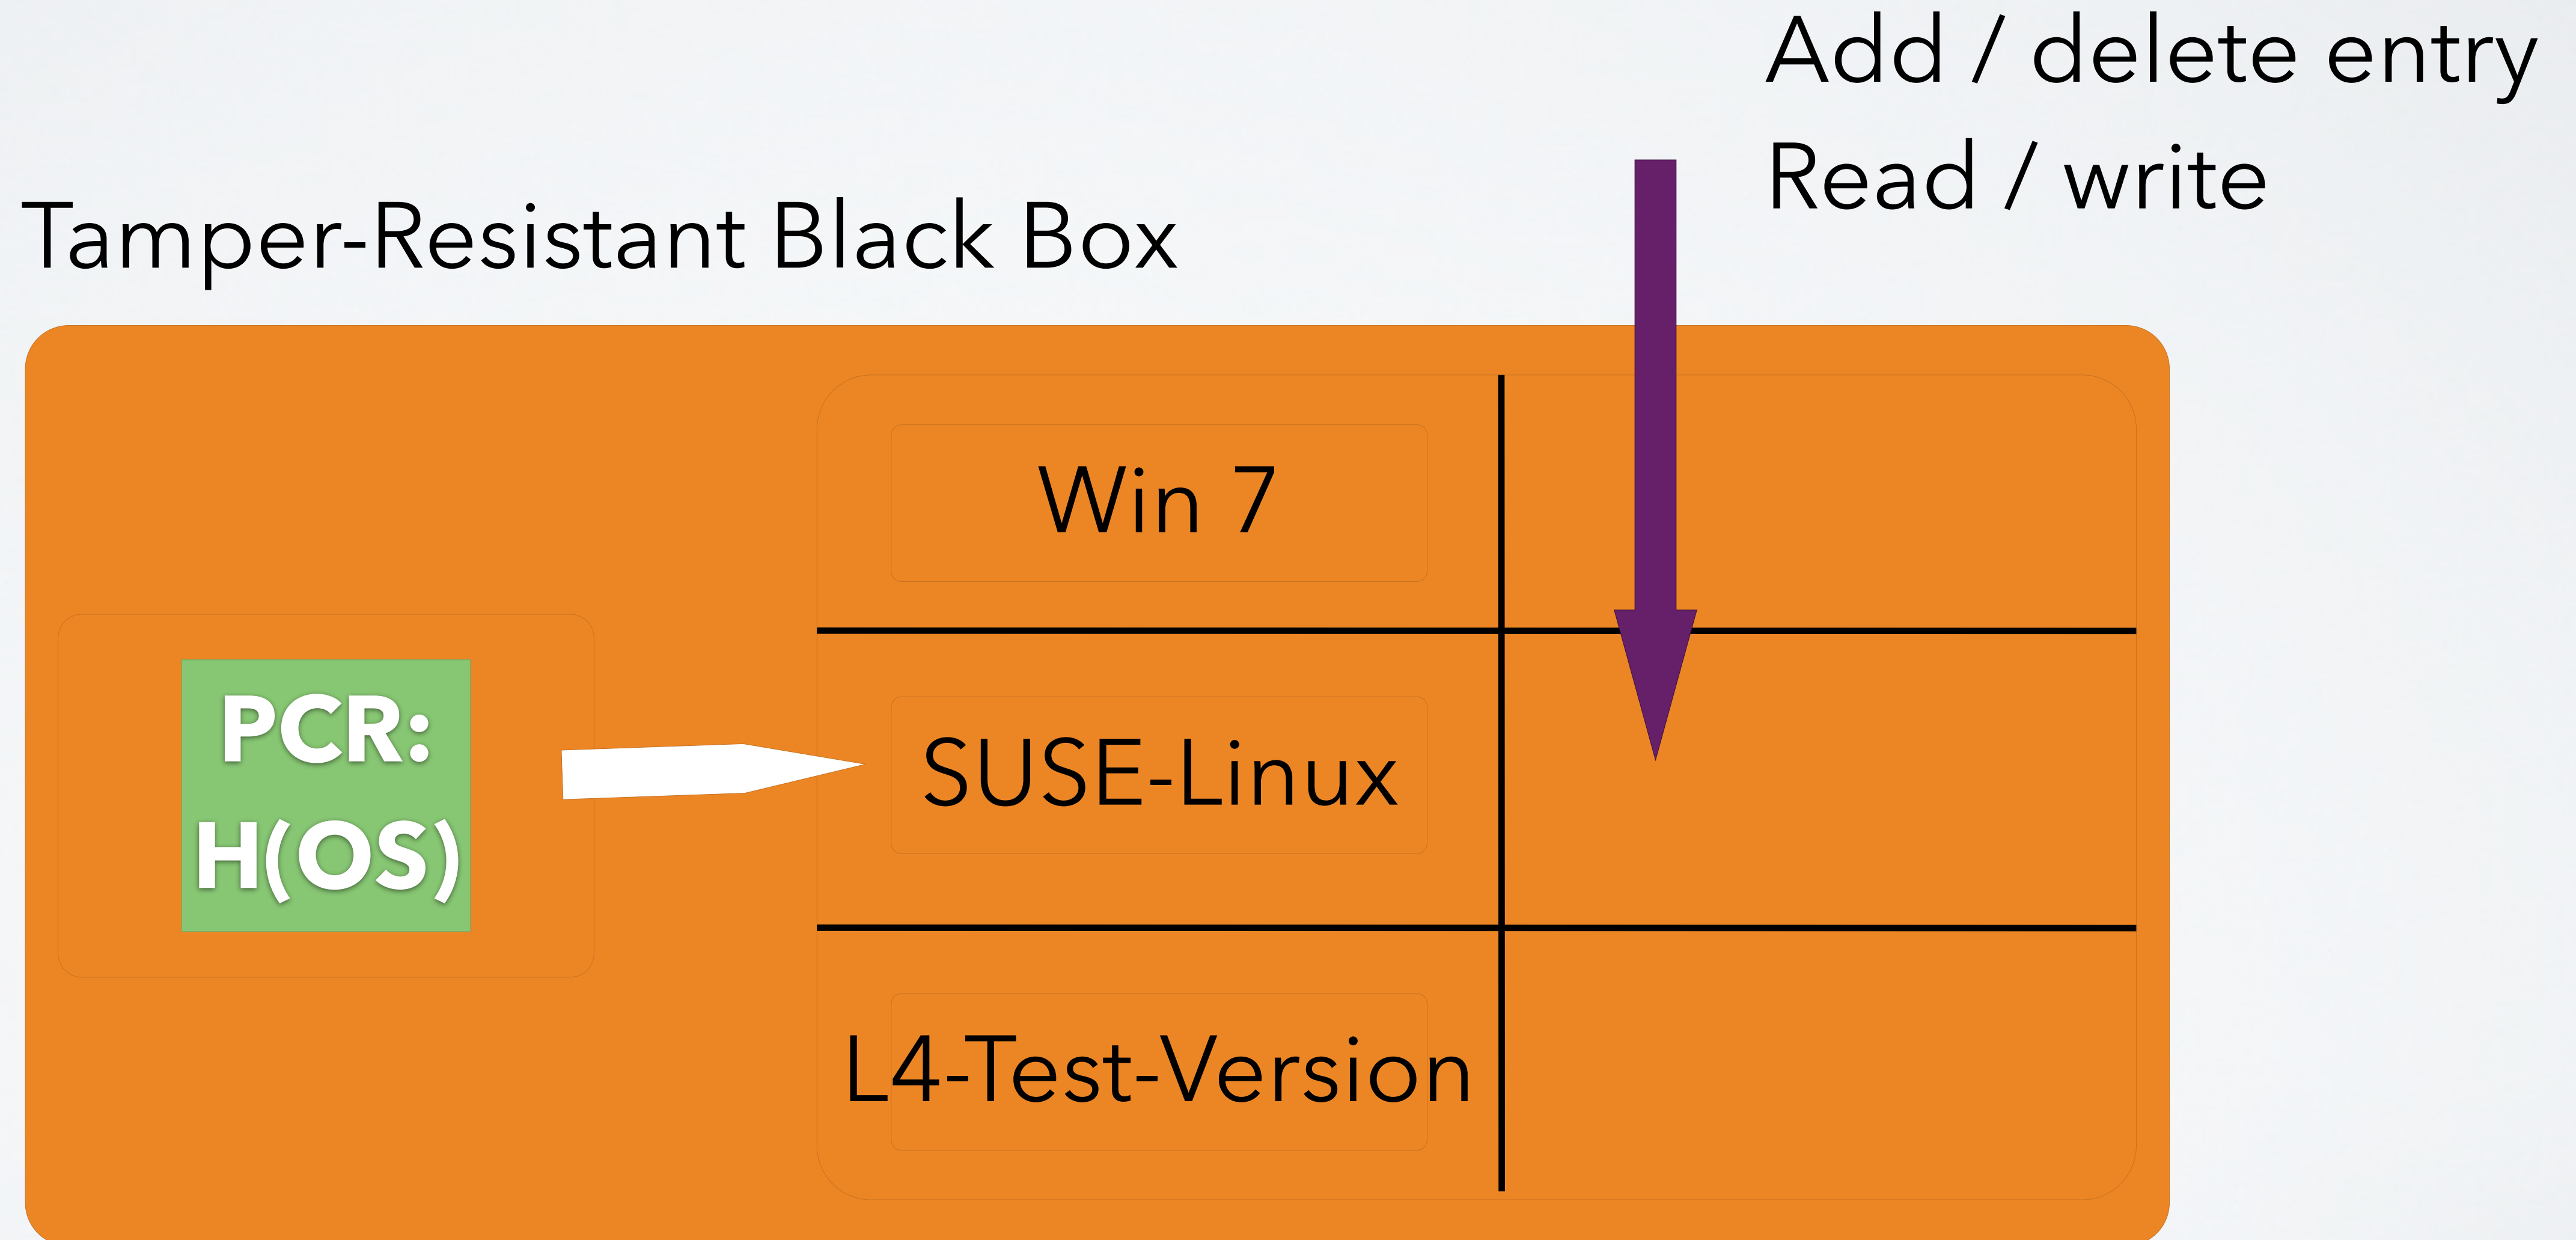

Tamper-Resistant Black Box

Add / delete entry  
Read / write

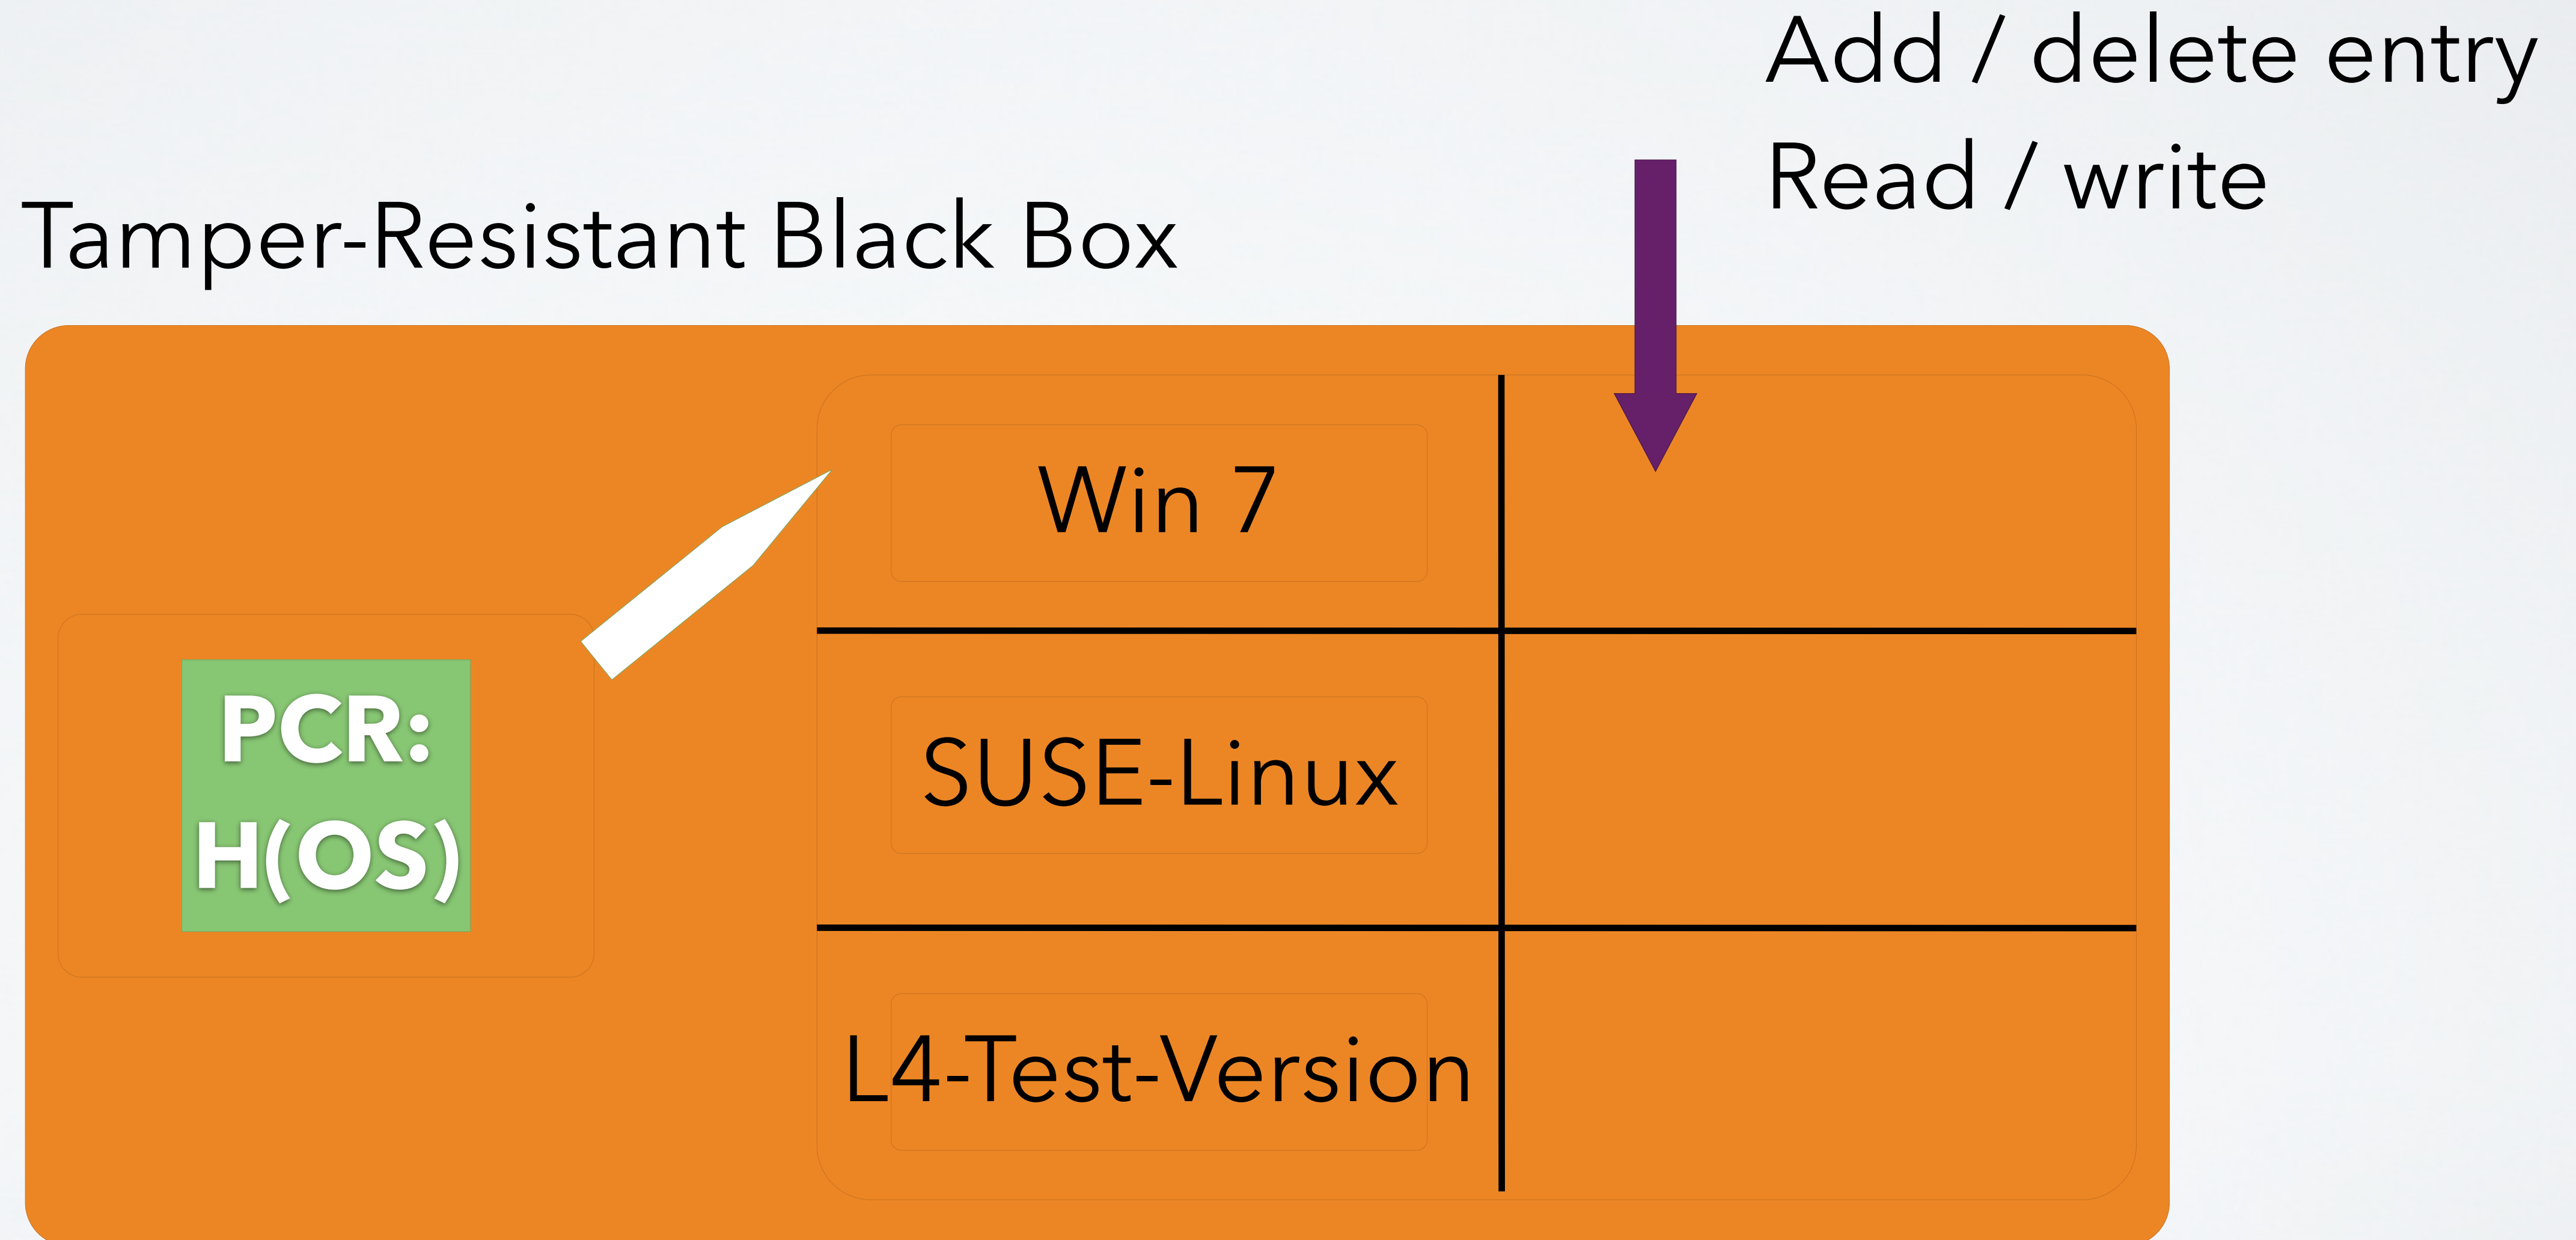

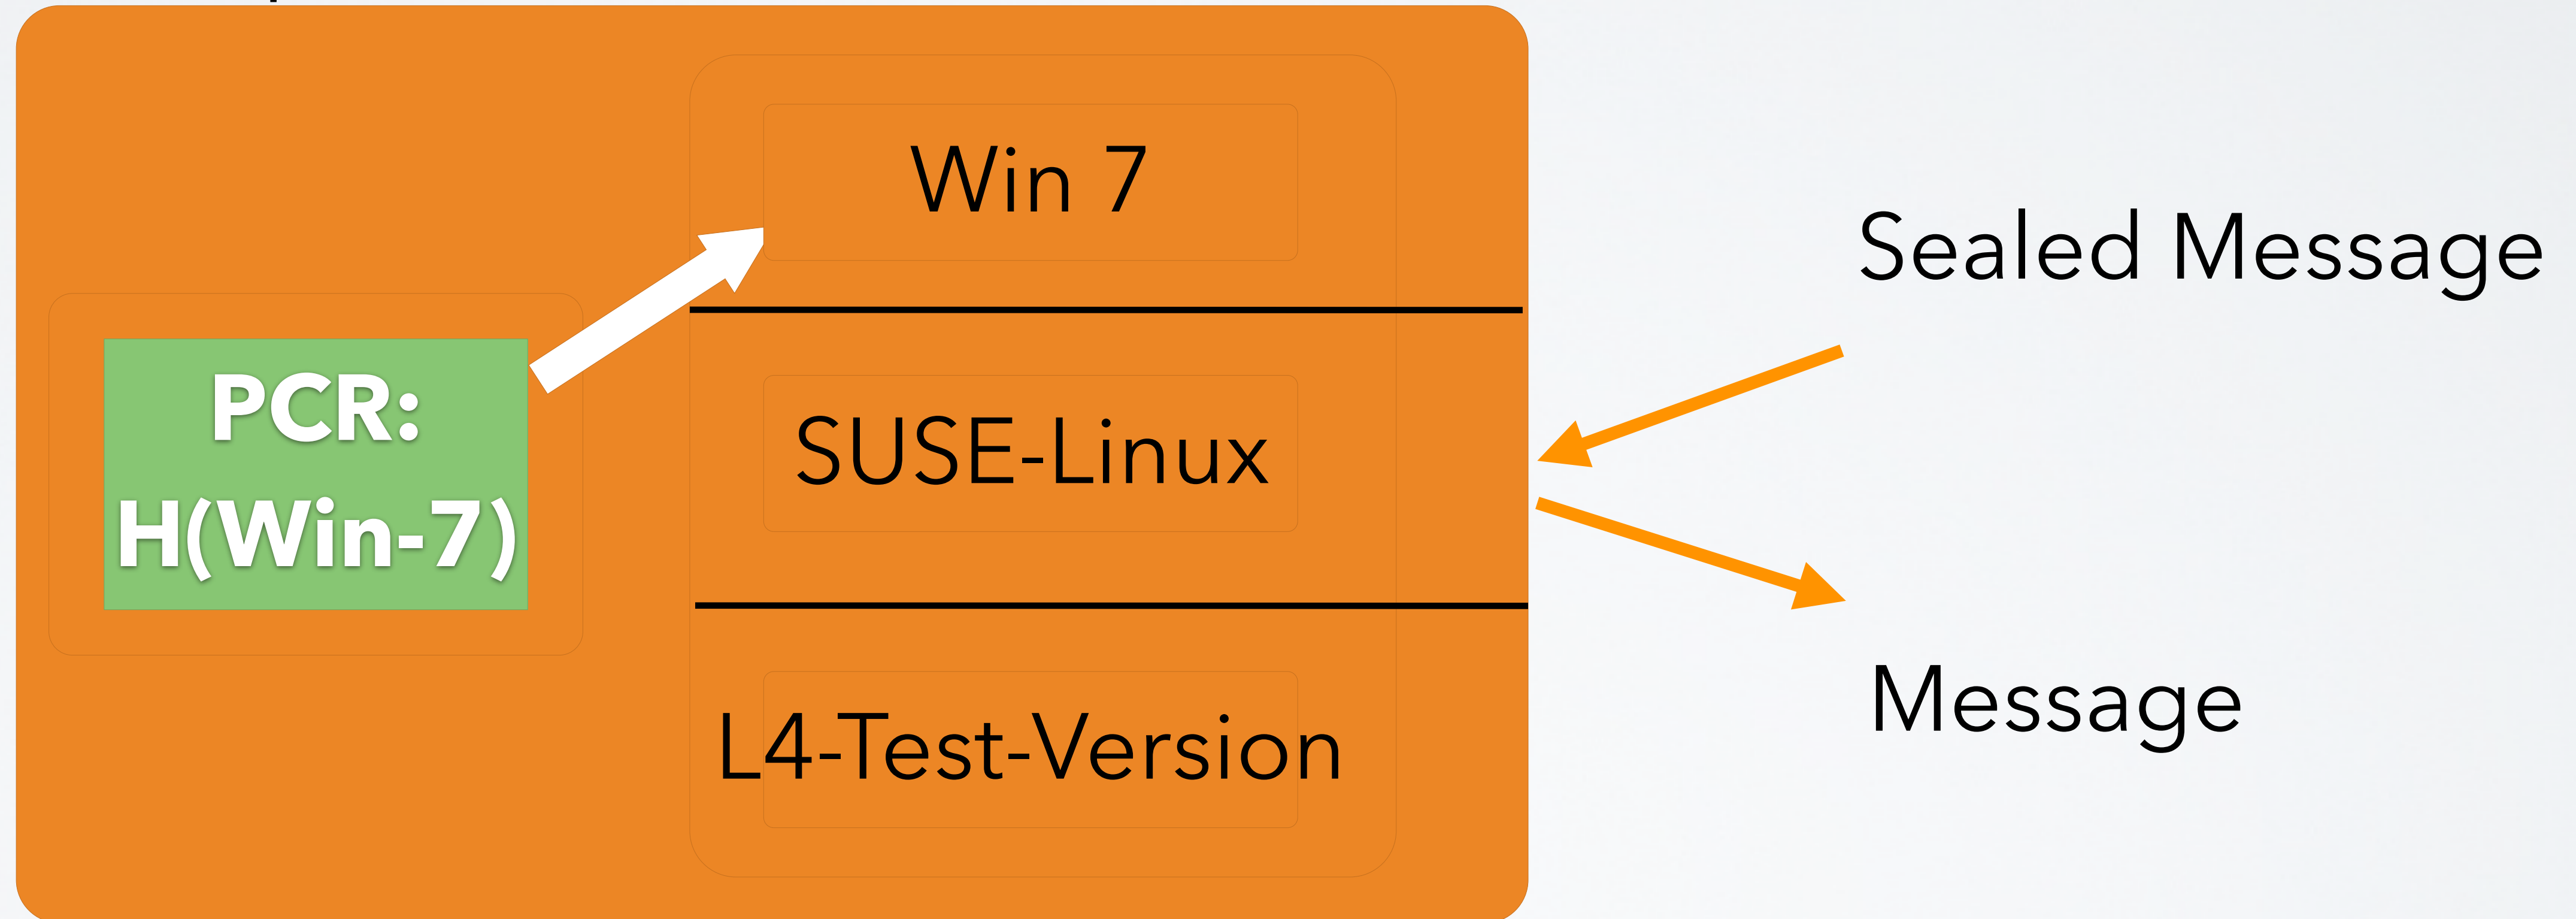

# Sealed Memory Principle

# Sealed Memory Principle

Tamper-resistant black box

TRB generates  
symmetric Storage Key  
never leaves chip

## Seal(message):

```
encrypt("PCR, message", S) → "sealed_message";  
emit sealed_message
```

## Unseal(sealed\_message):

```
decrypt(sealed_message, S) → "SealTime_PCR,message";  
If SealTime_PCR == PCR  
  then emit message  
  else abort
```

Seal(message, FUTURE\_Config):

```
encrypt("FUTURE_Config, message", S) → "sealed_message";  
emit sealed_message
```

"seals" information such that it can be unsealed by a future configuration

(for example: future OS version)

- Win8: Seal („SonyOS, Sony-Secret“)  
→ SealedMessage (store it on disk)
- L4: Unseal (SealedMessage)  
→ SonyOS, Sony-Secret  
→ PCR#SonyOS  
→ abort
- SonyOS: Unseal(SealedMessage  
→ SonyOS, Sony-Secret  
→ PCR==SonyOS

Ideally, includes CPU, Memory, ...

Current practice

- Additional physical protection, for example IBM 4758 ...  
look it up in Wikipedia
- HW support:
  - TPM:  
separate "Trusted Platform Modules" (replacing BIOS breaks TRB)
  - Add a new privilege mode: ARM TrustZone
  - raise to user processes: Intel SGX

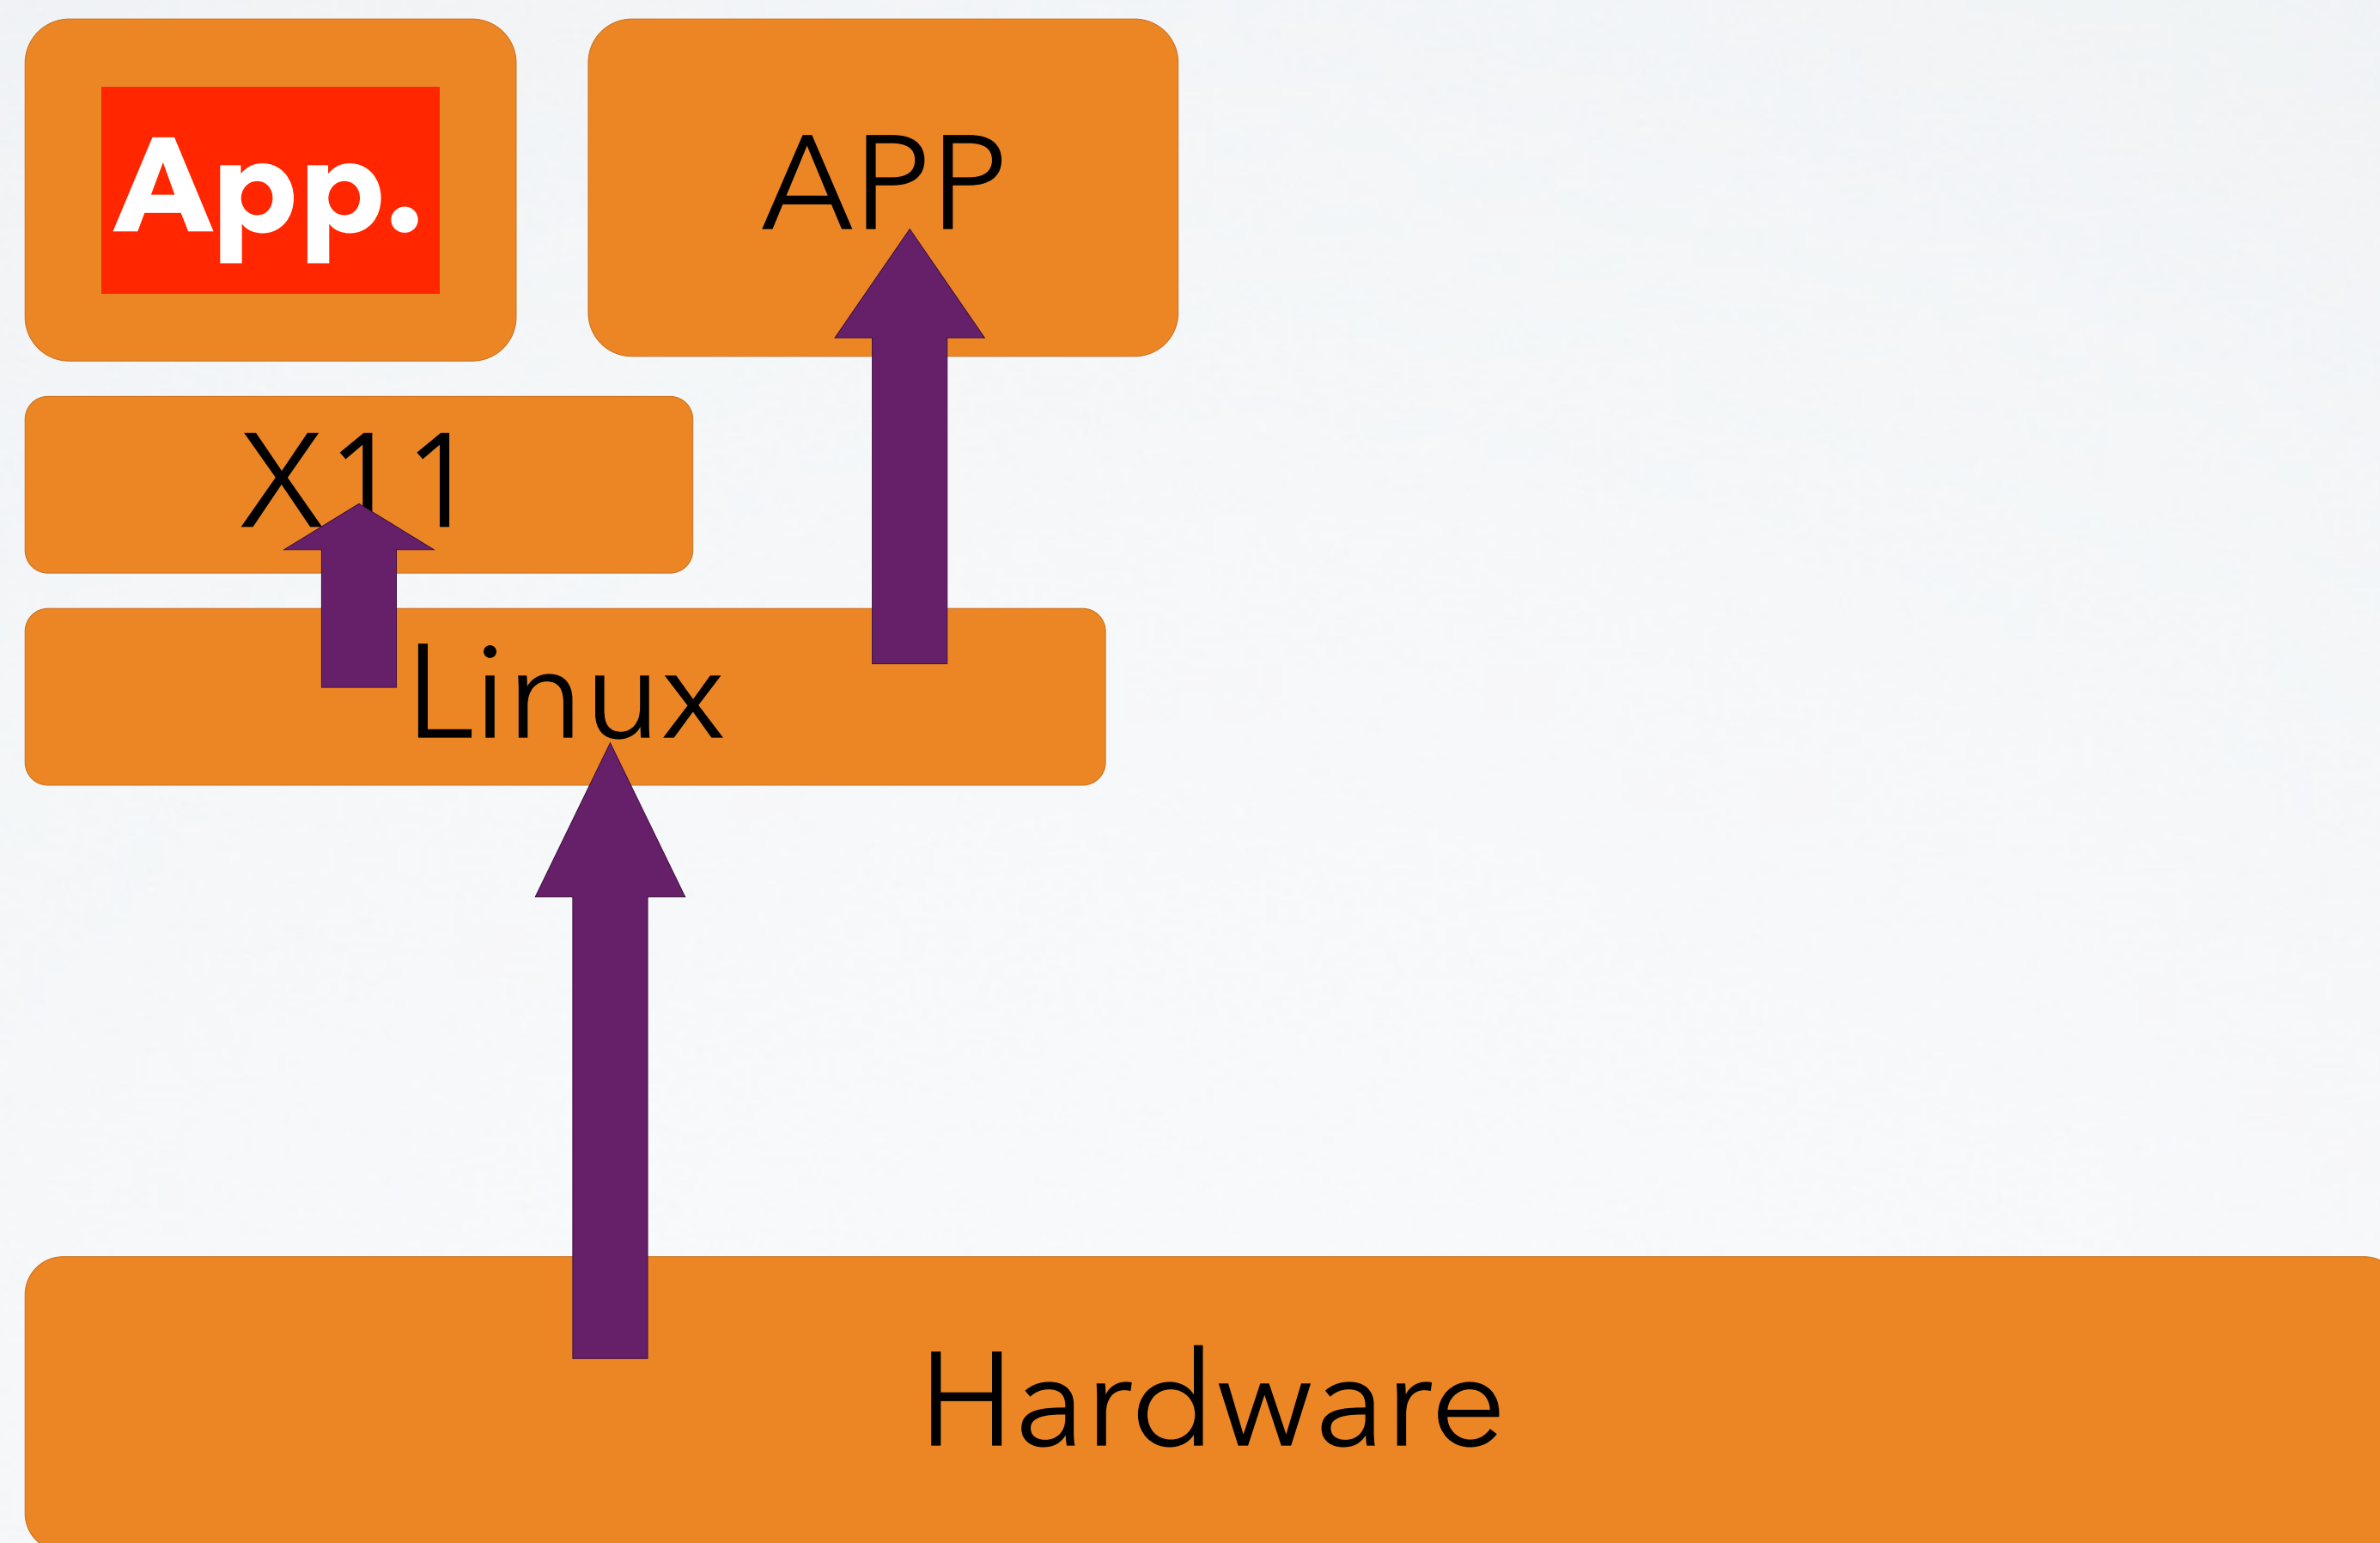

Principle Method:

separate critical Software

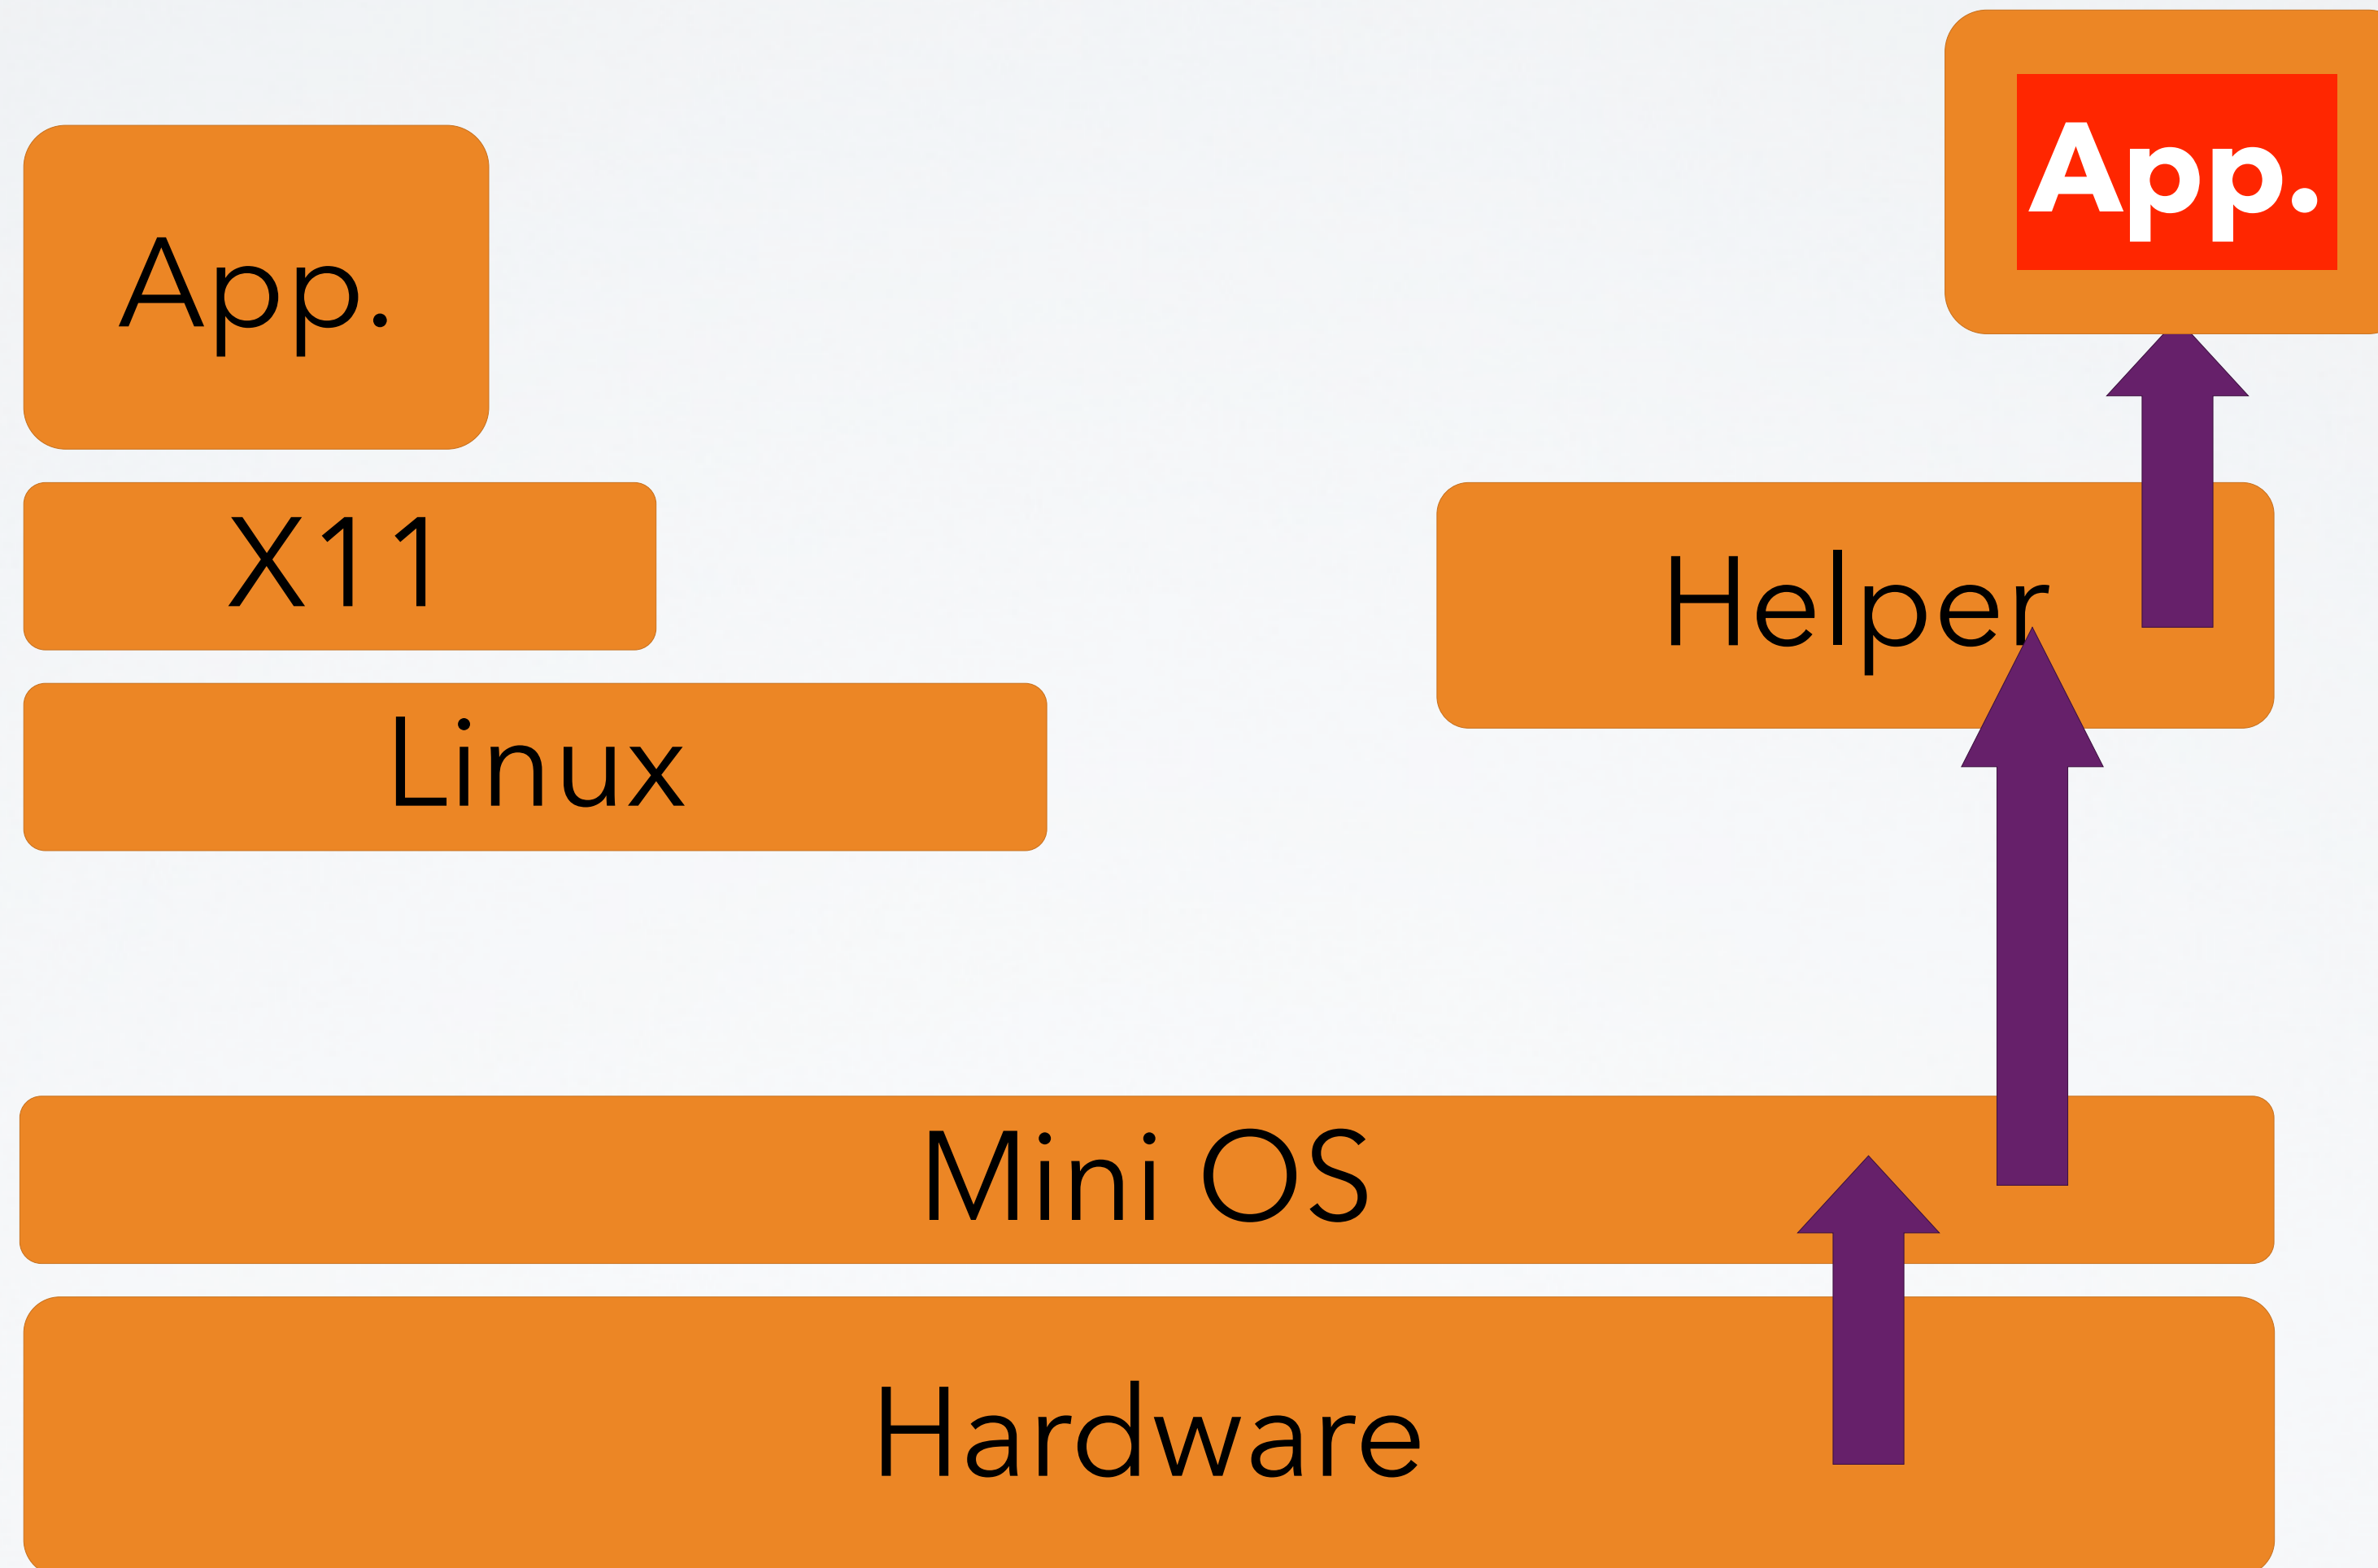

rely on small Trusted Computing Base

- Small OS kernels  
micro kernels, separation kernels, ....
- Hardware/Microcode Support

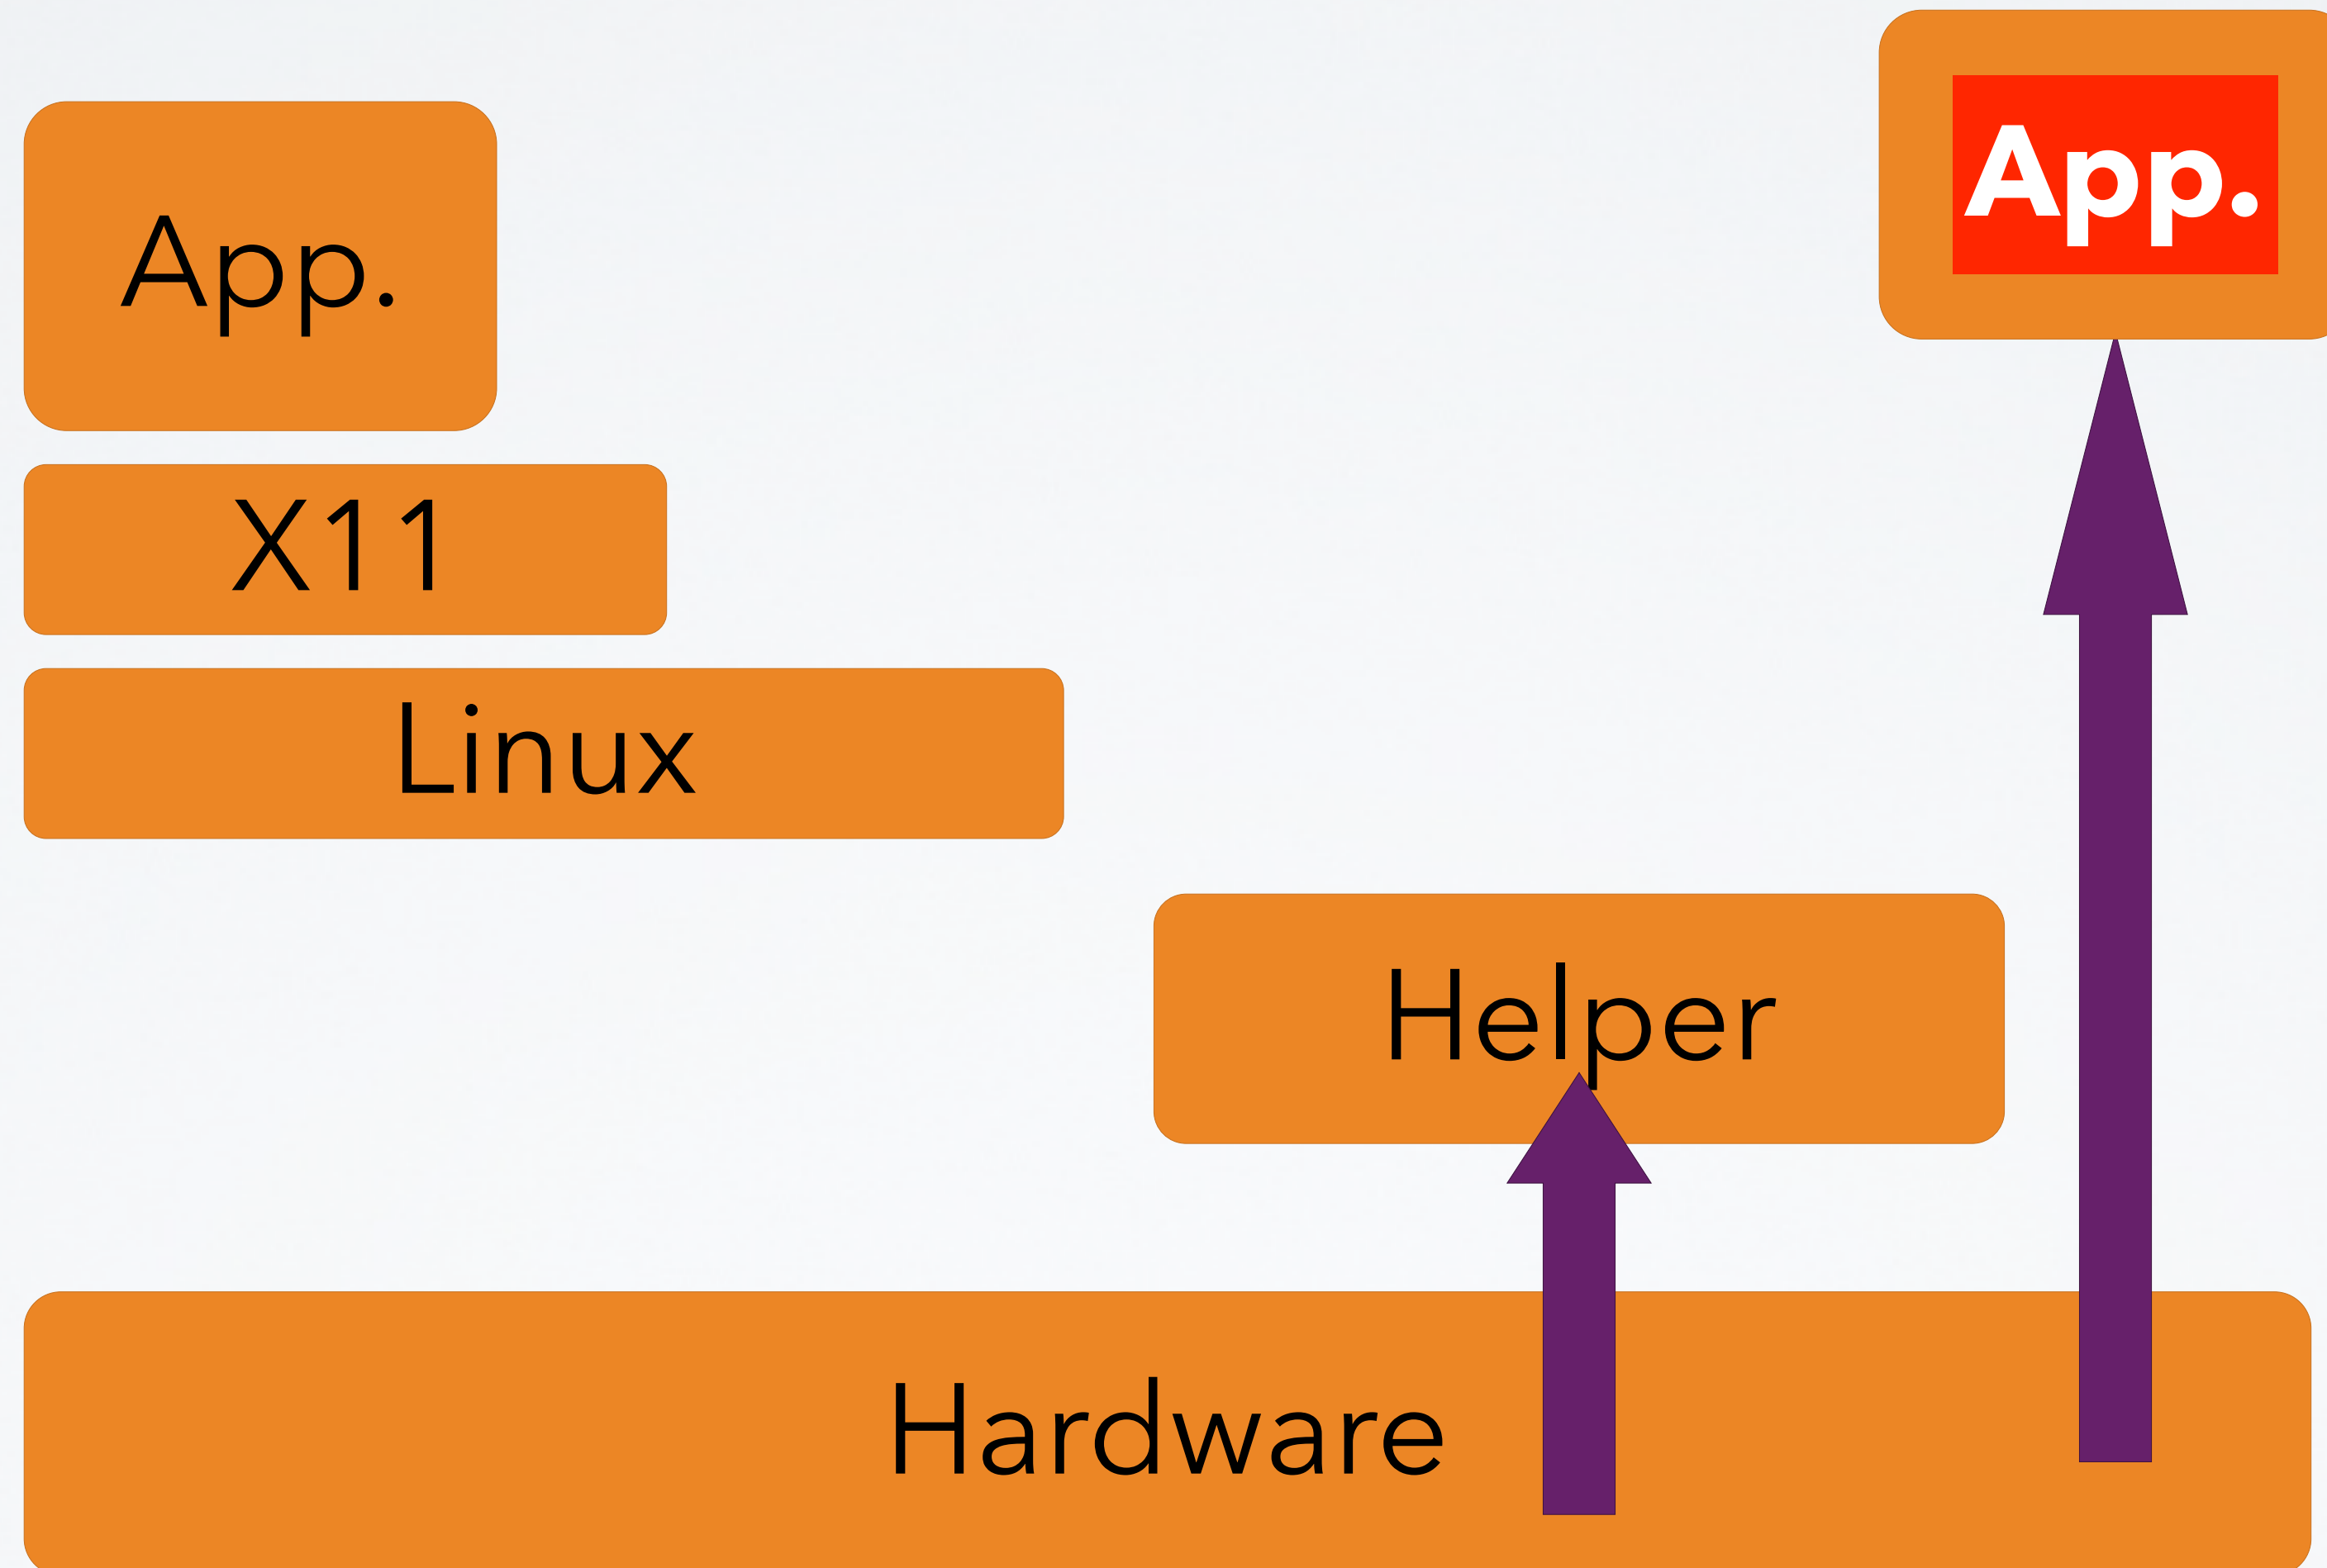

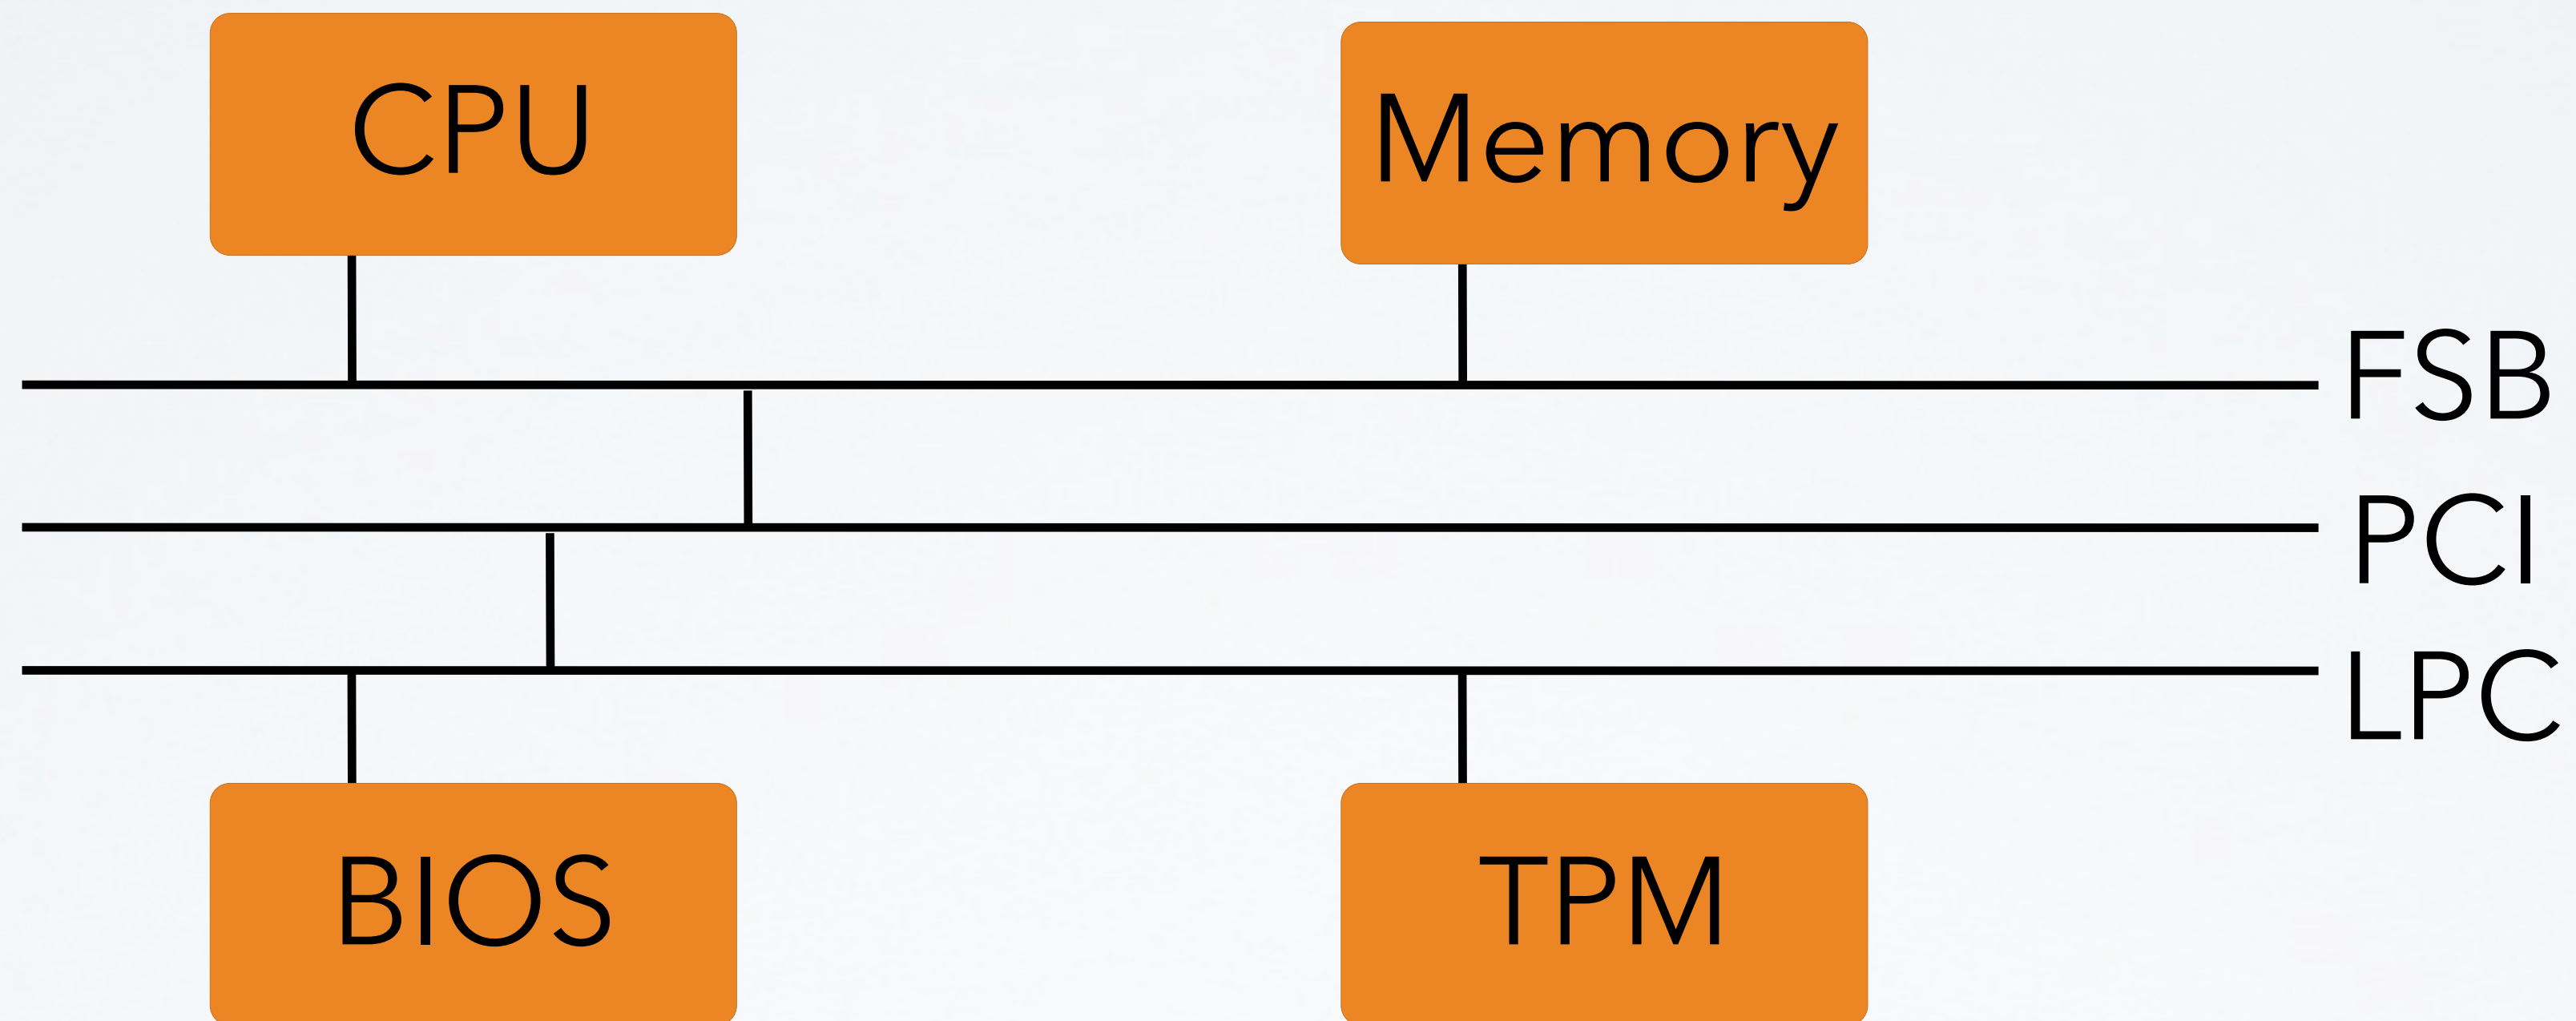

# Small Trusted Computing Base

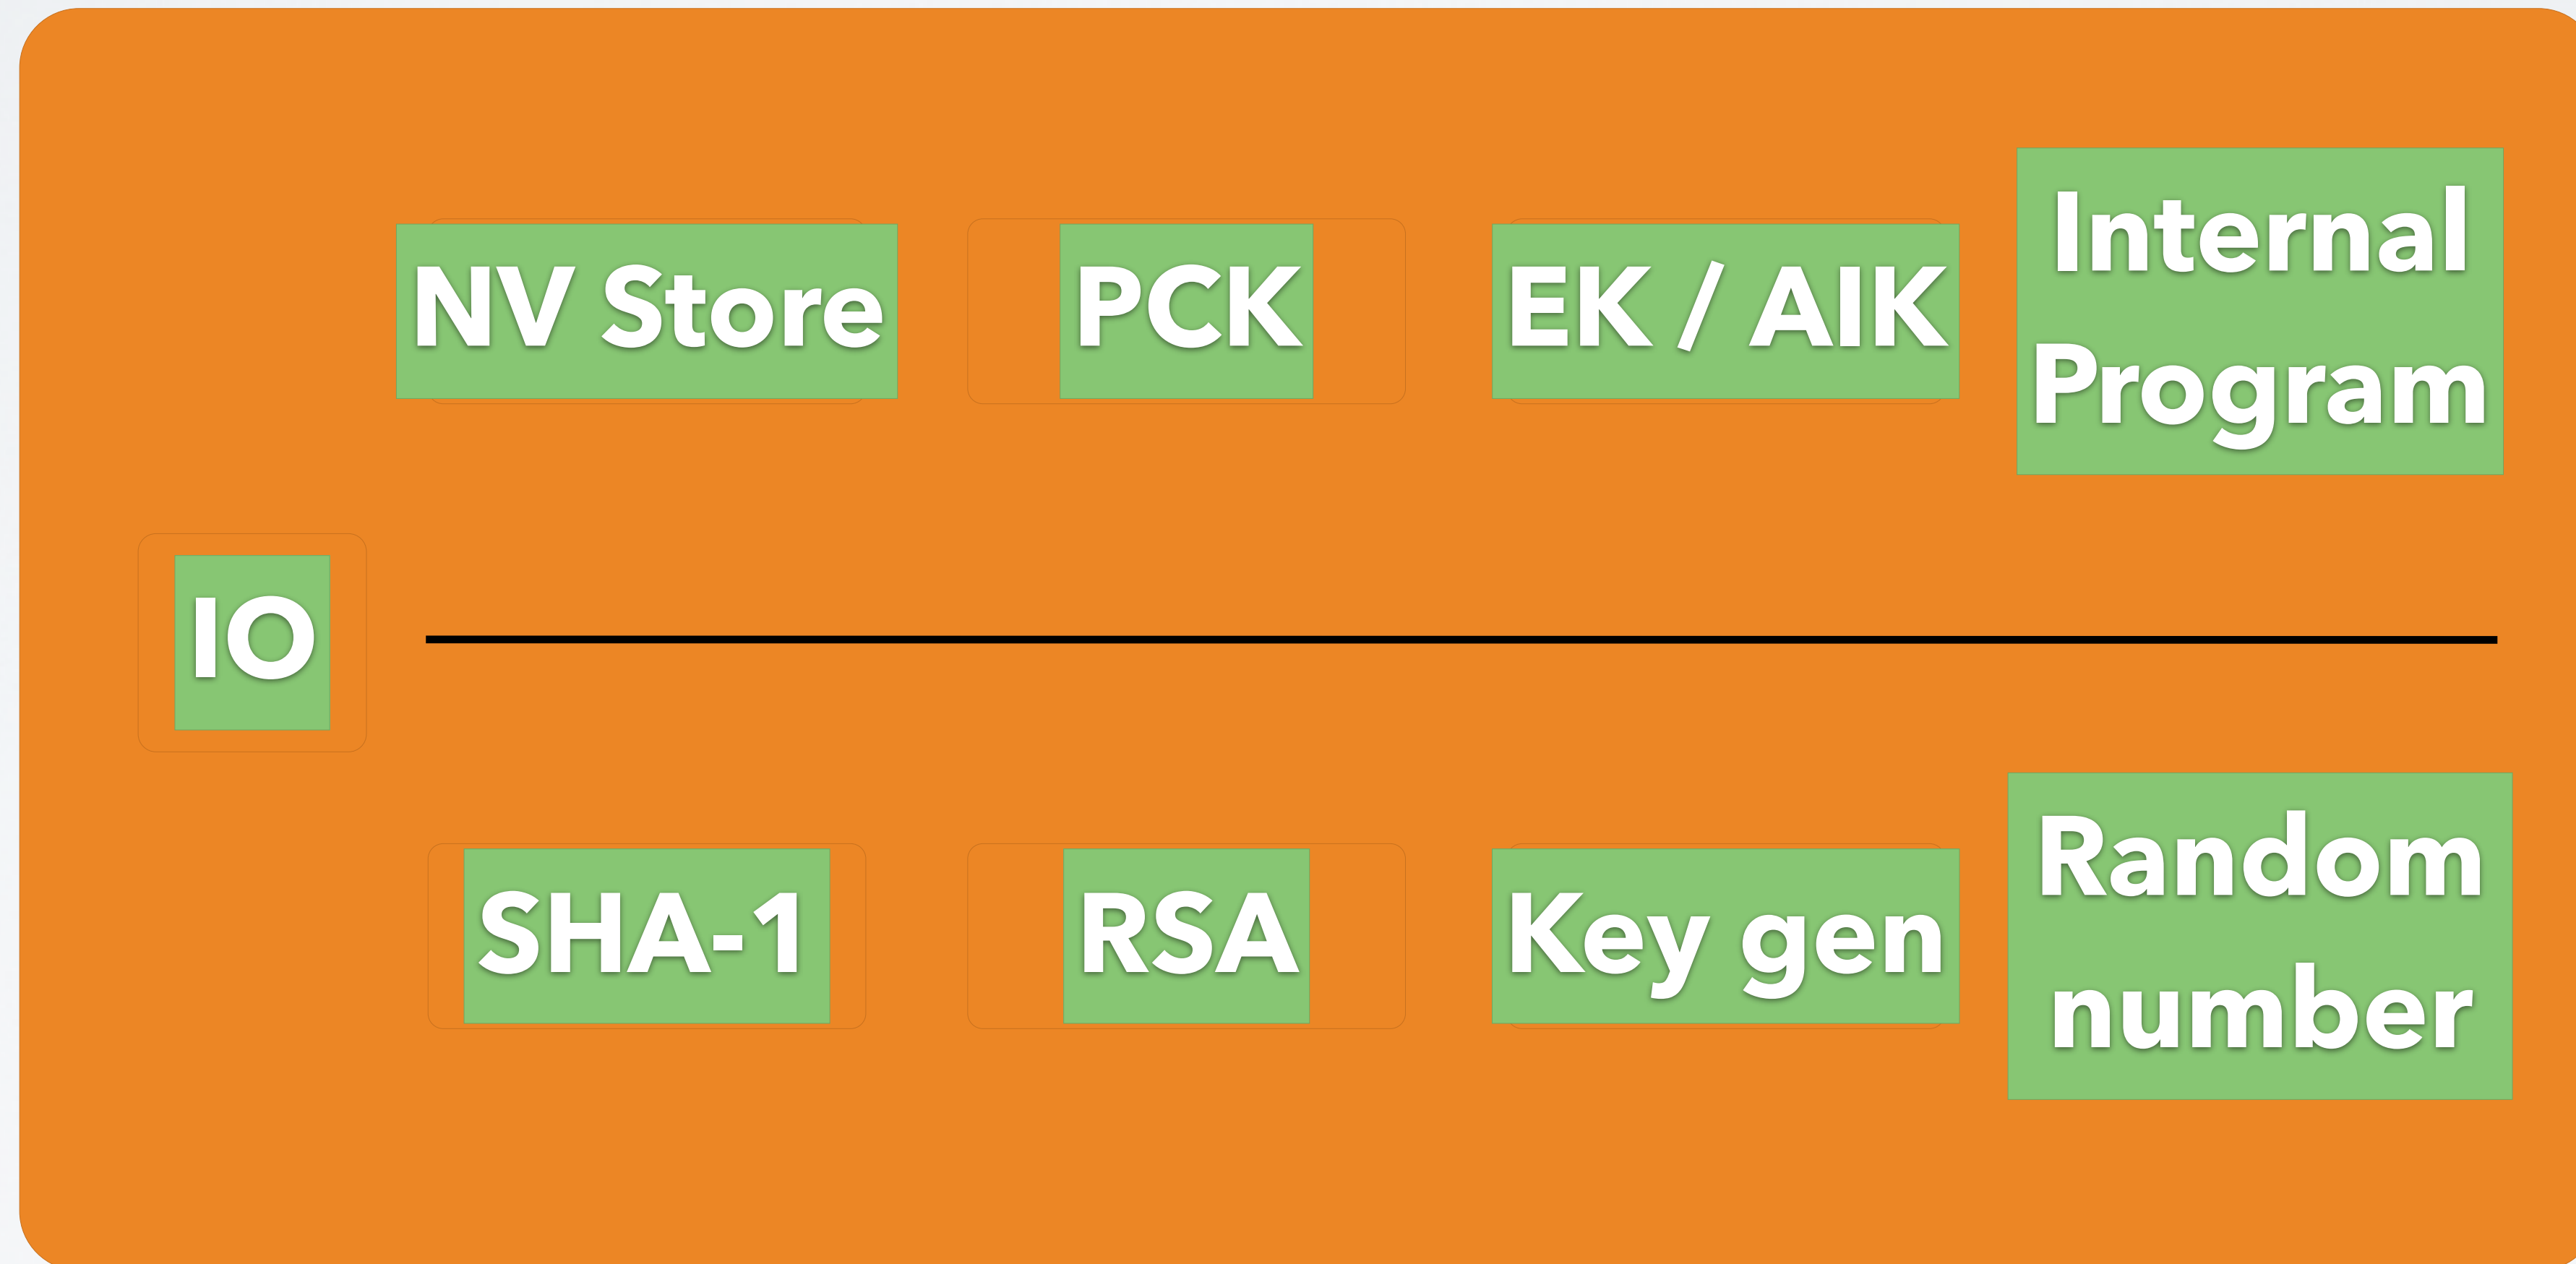

# Small Trusted Computing Base

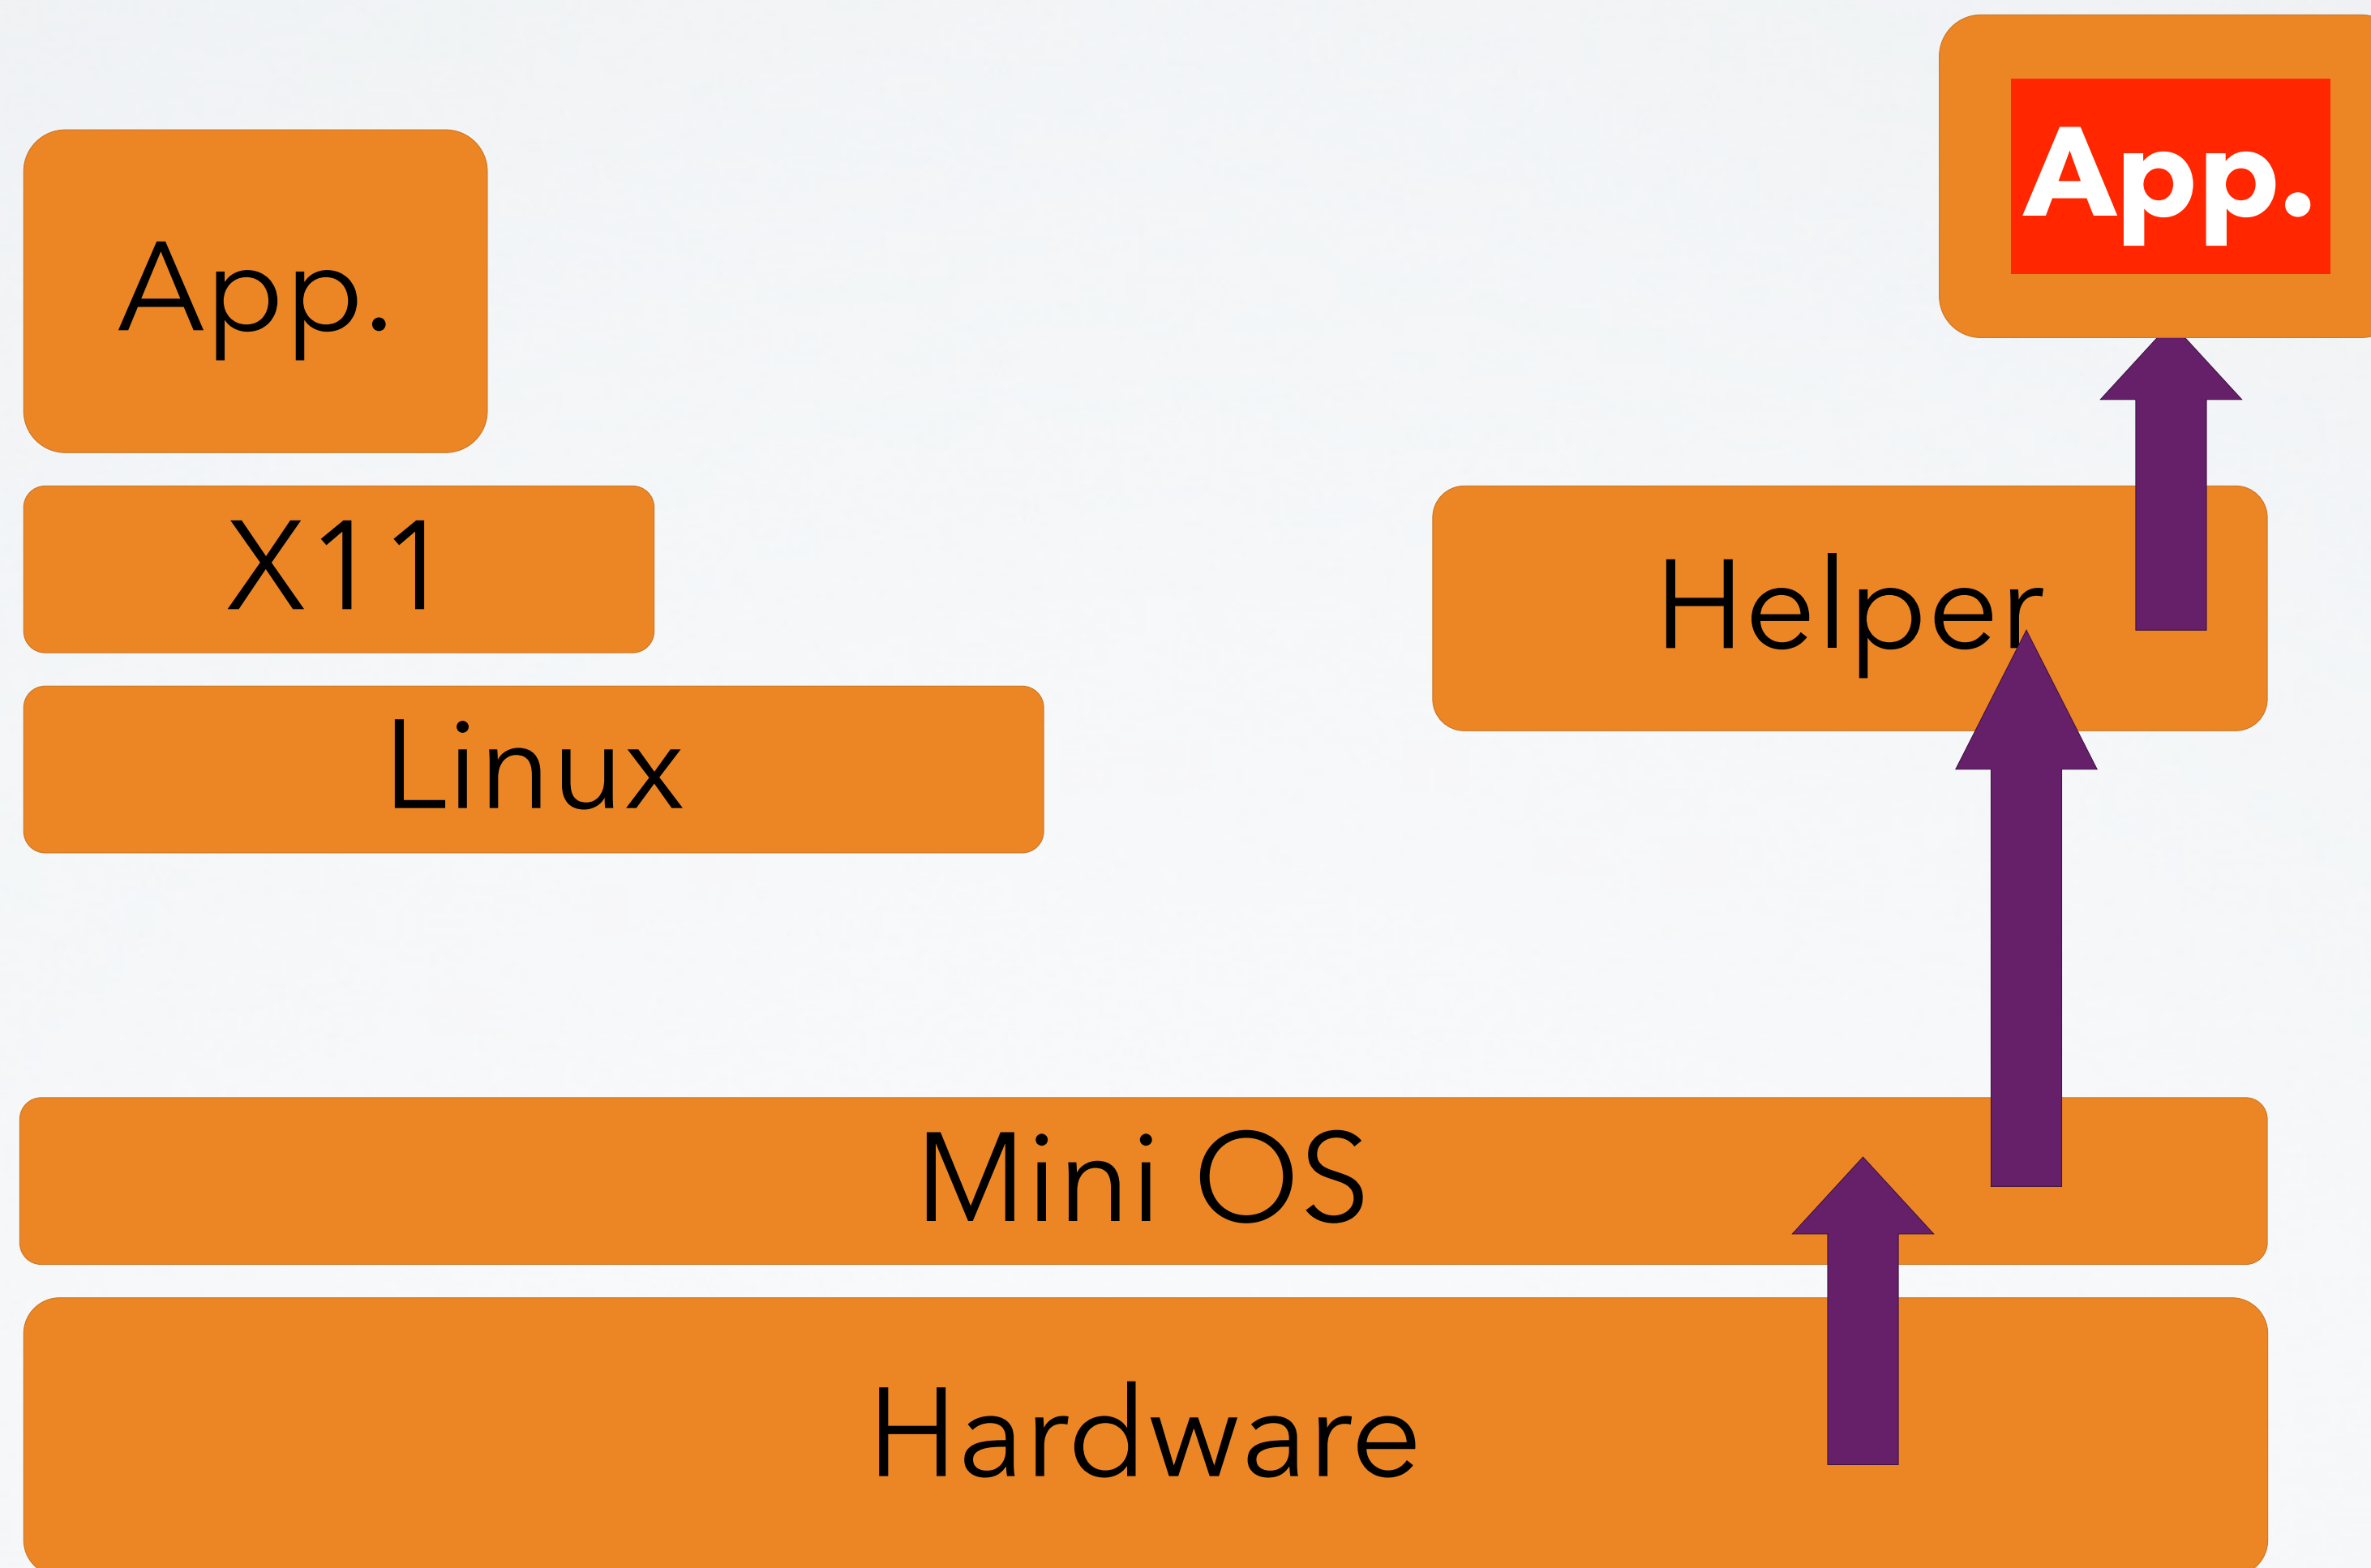

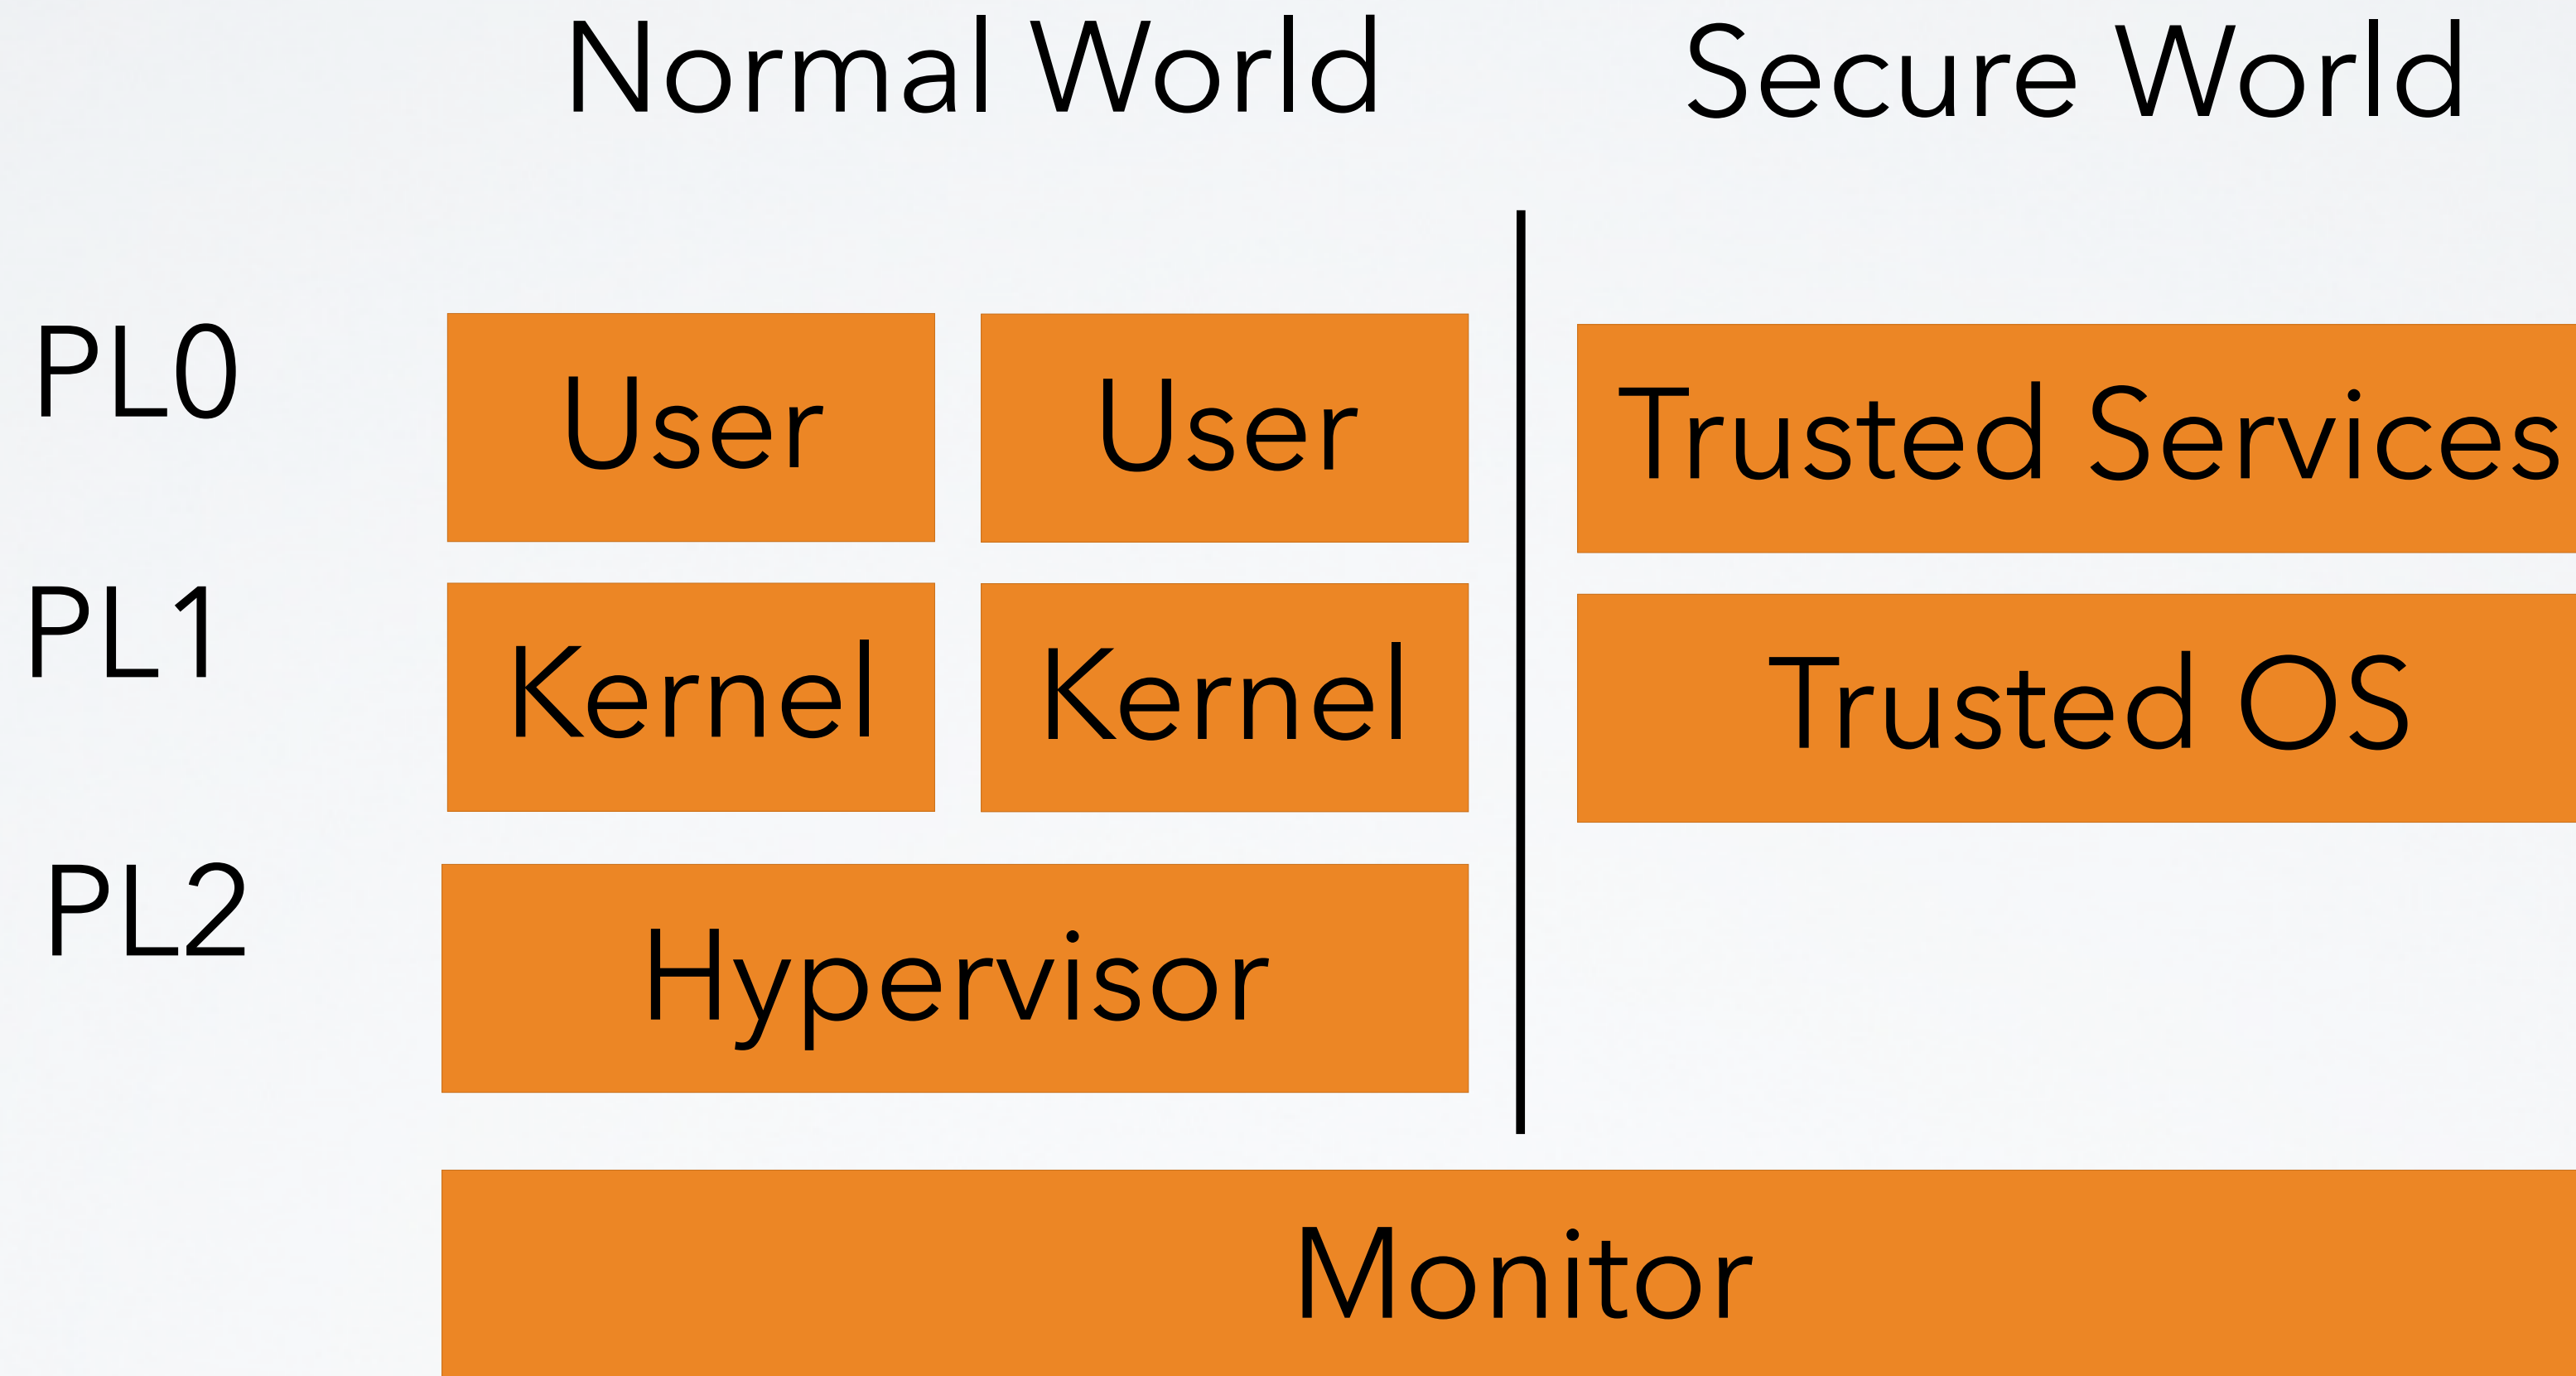

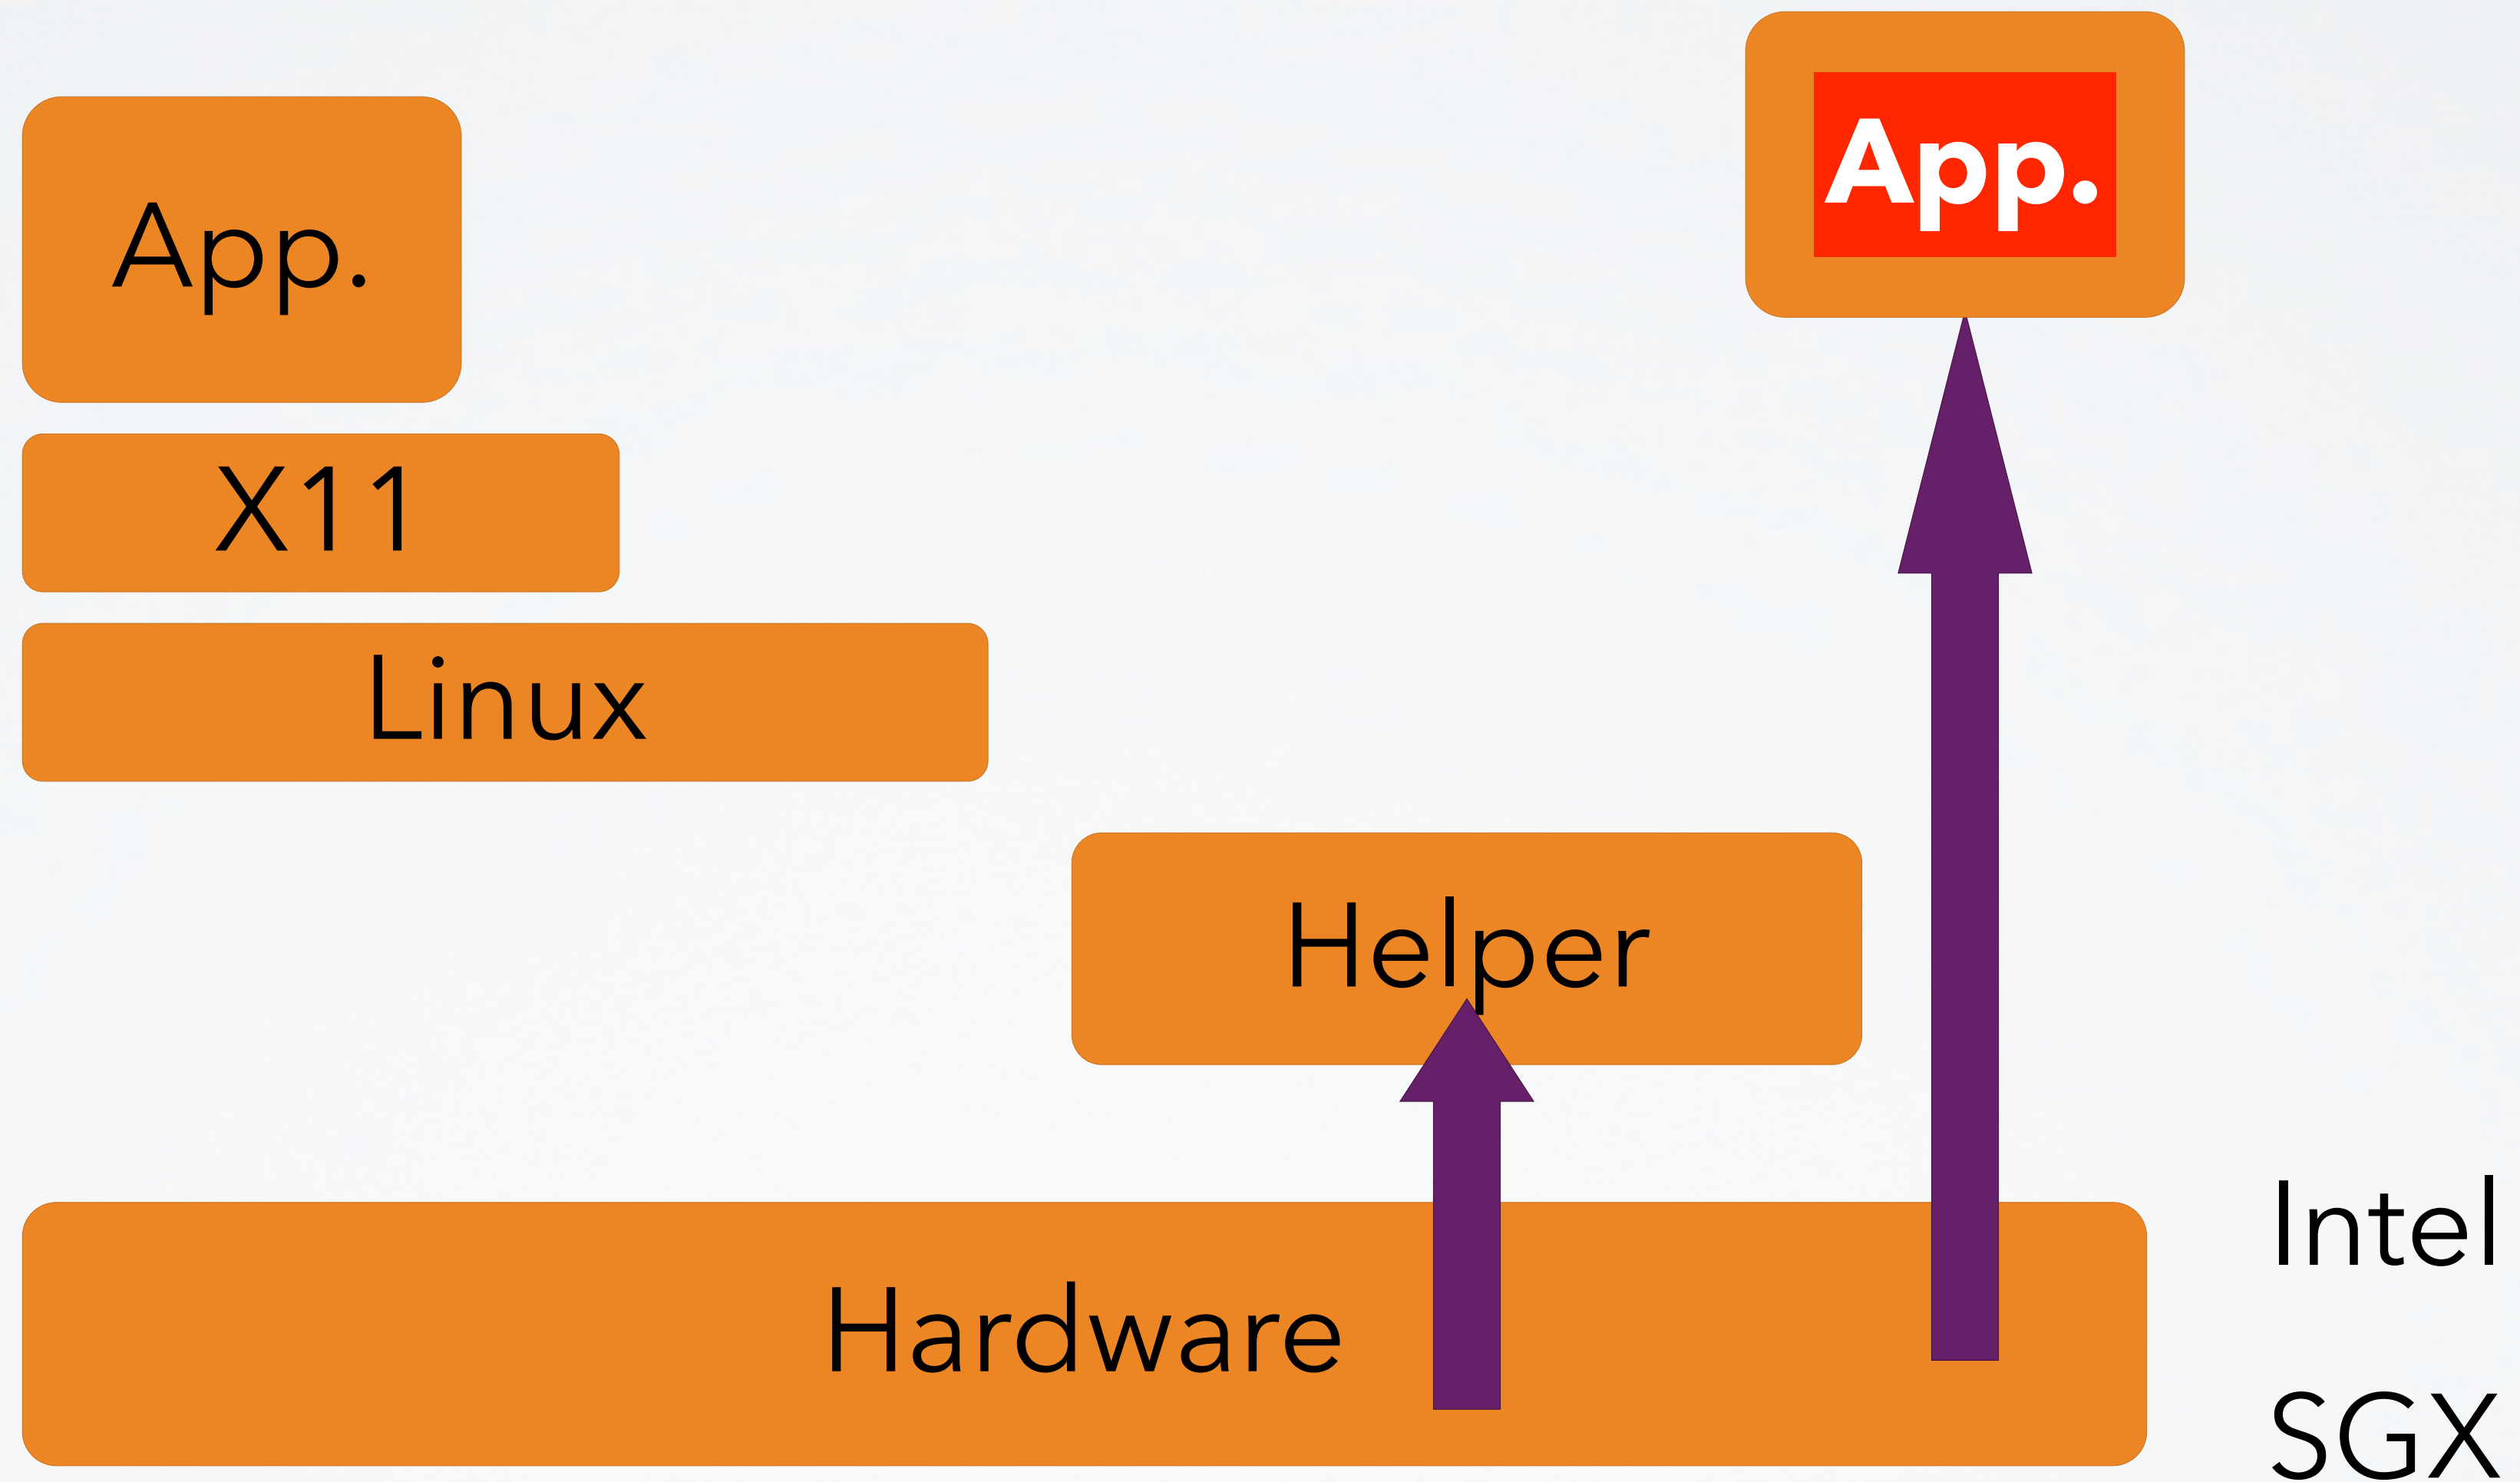

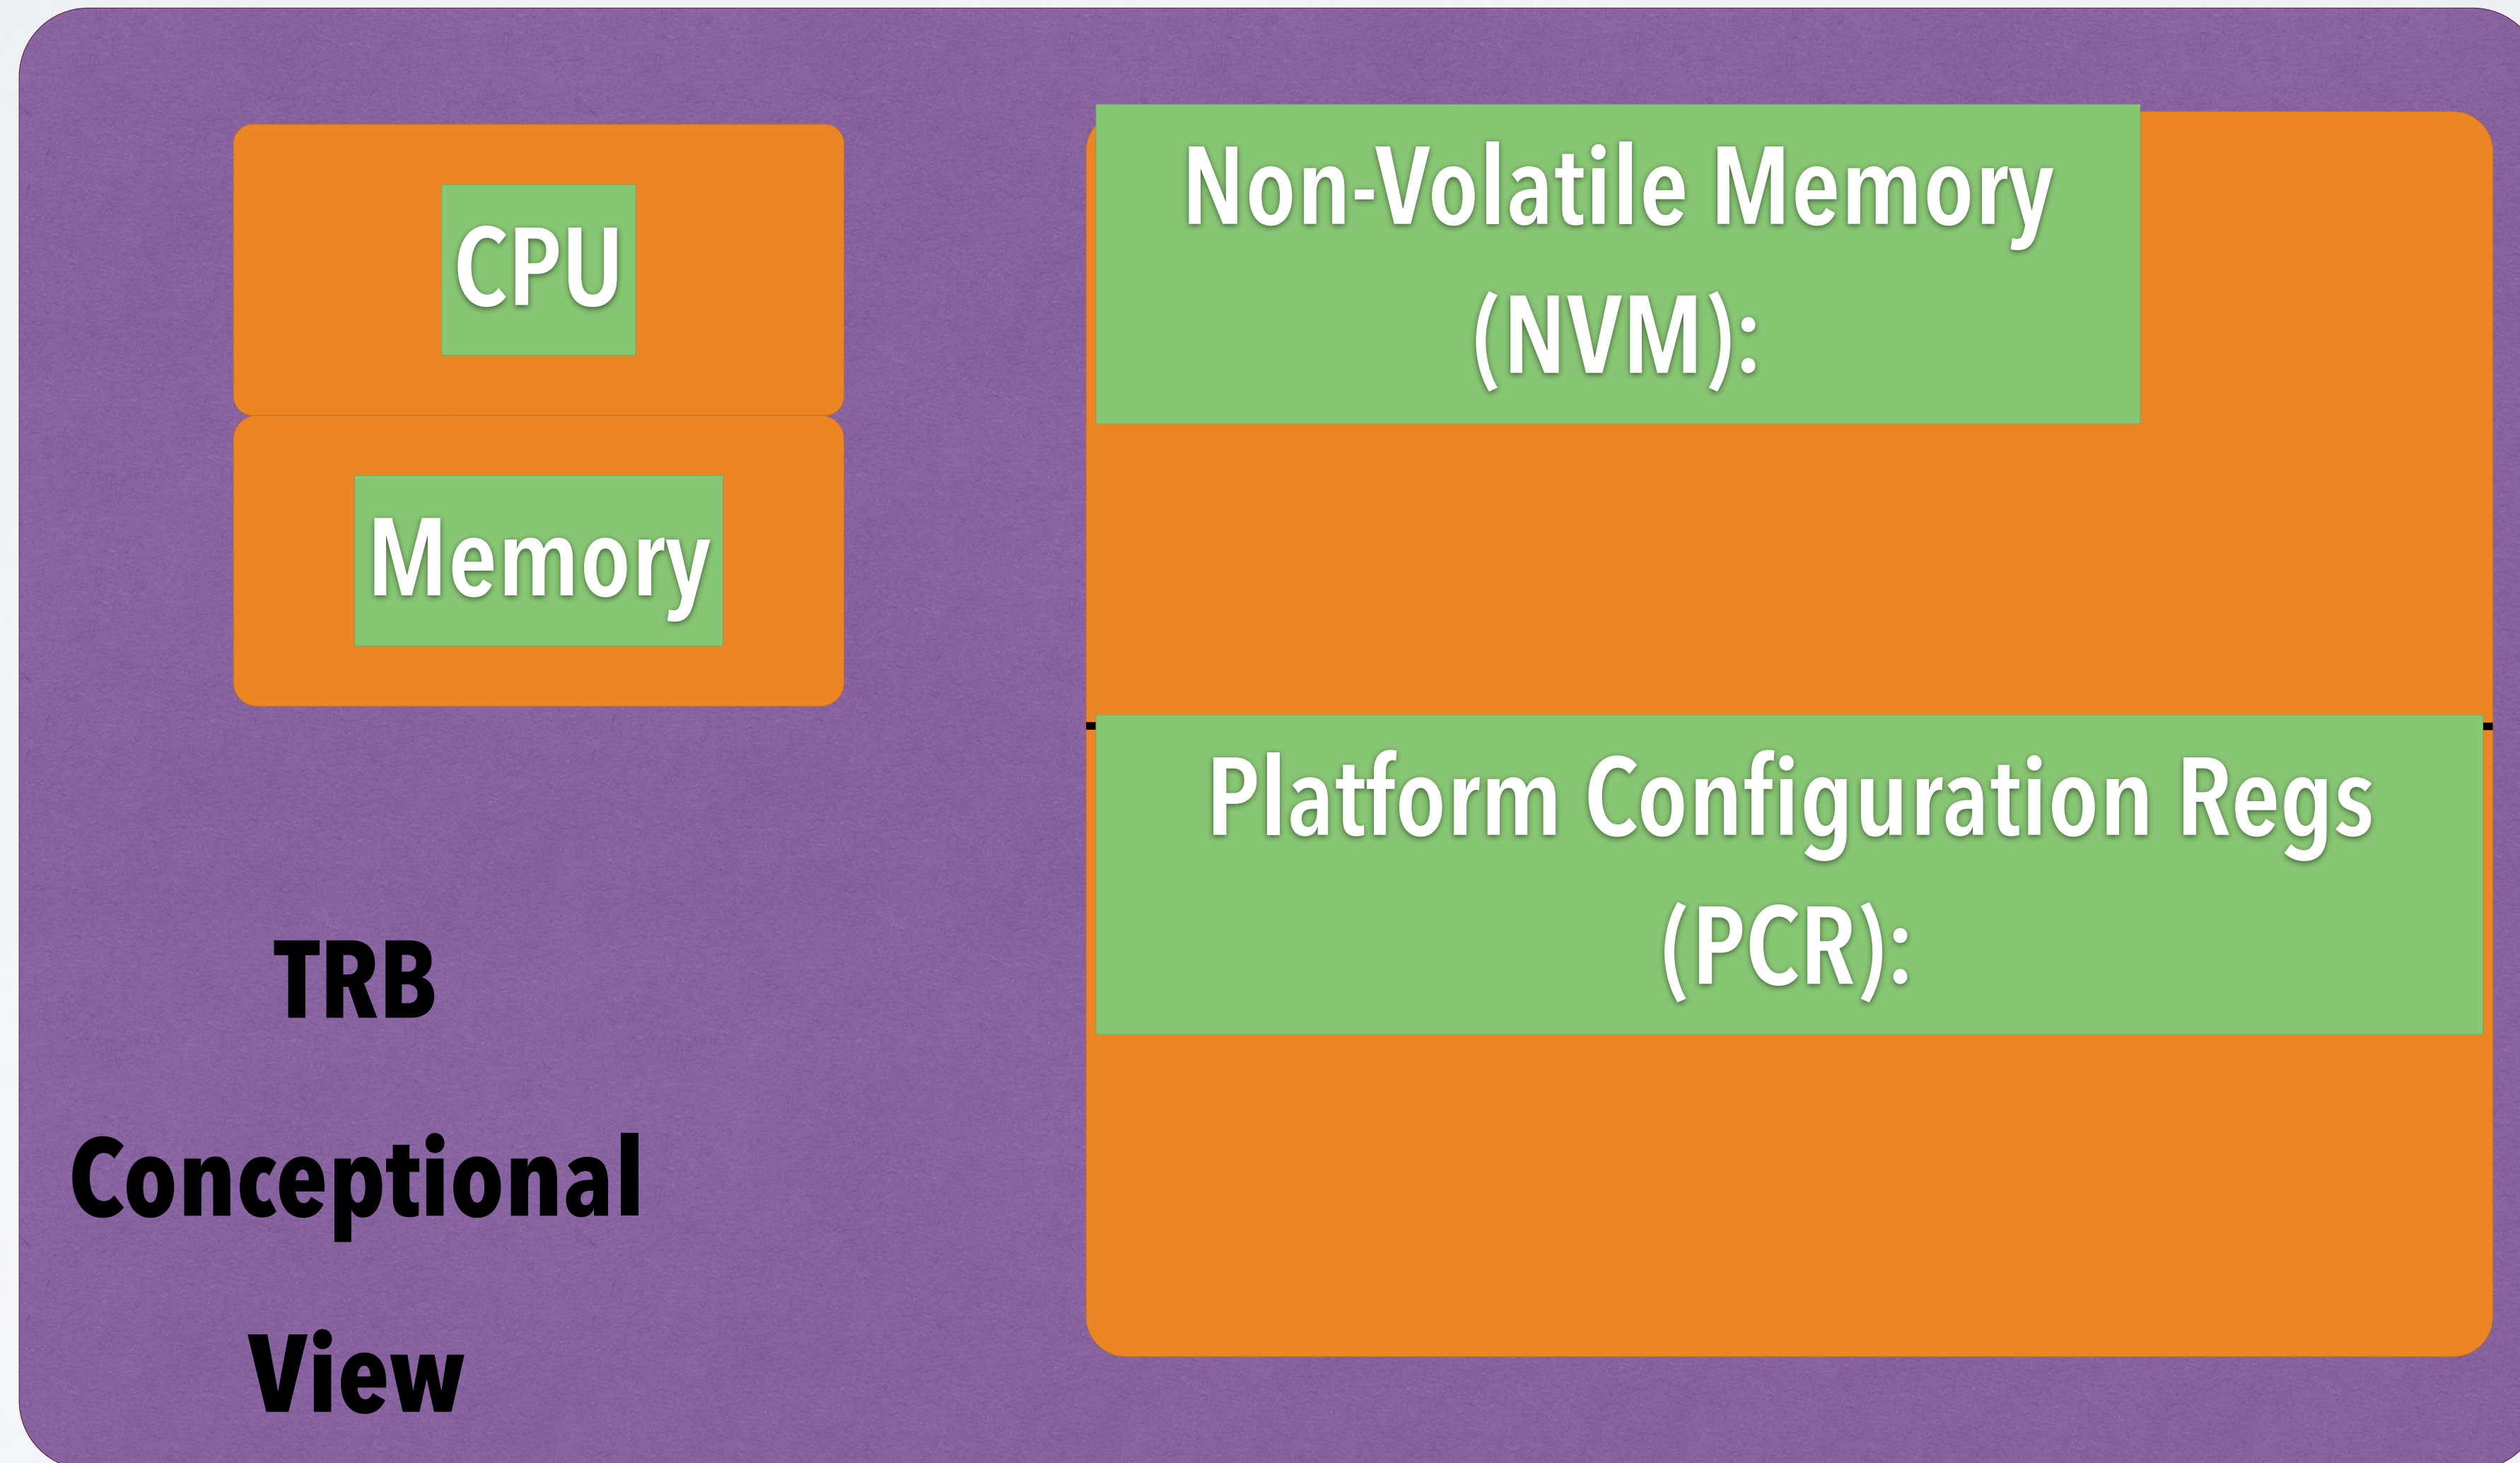

# Small Trusted Computing Base

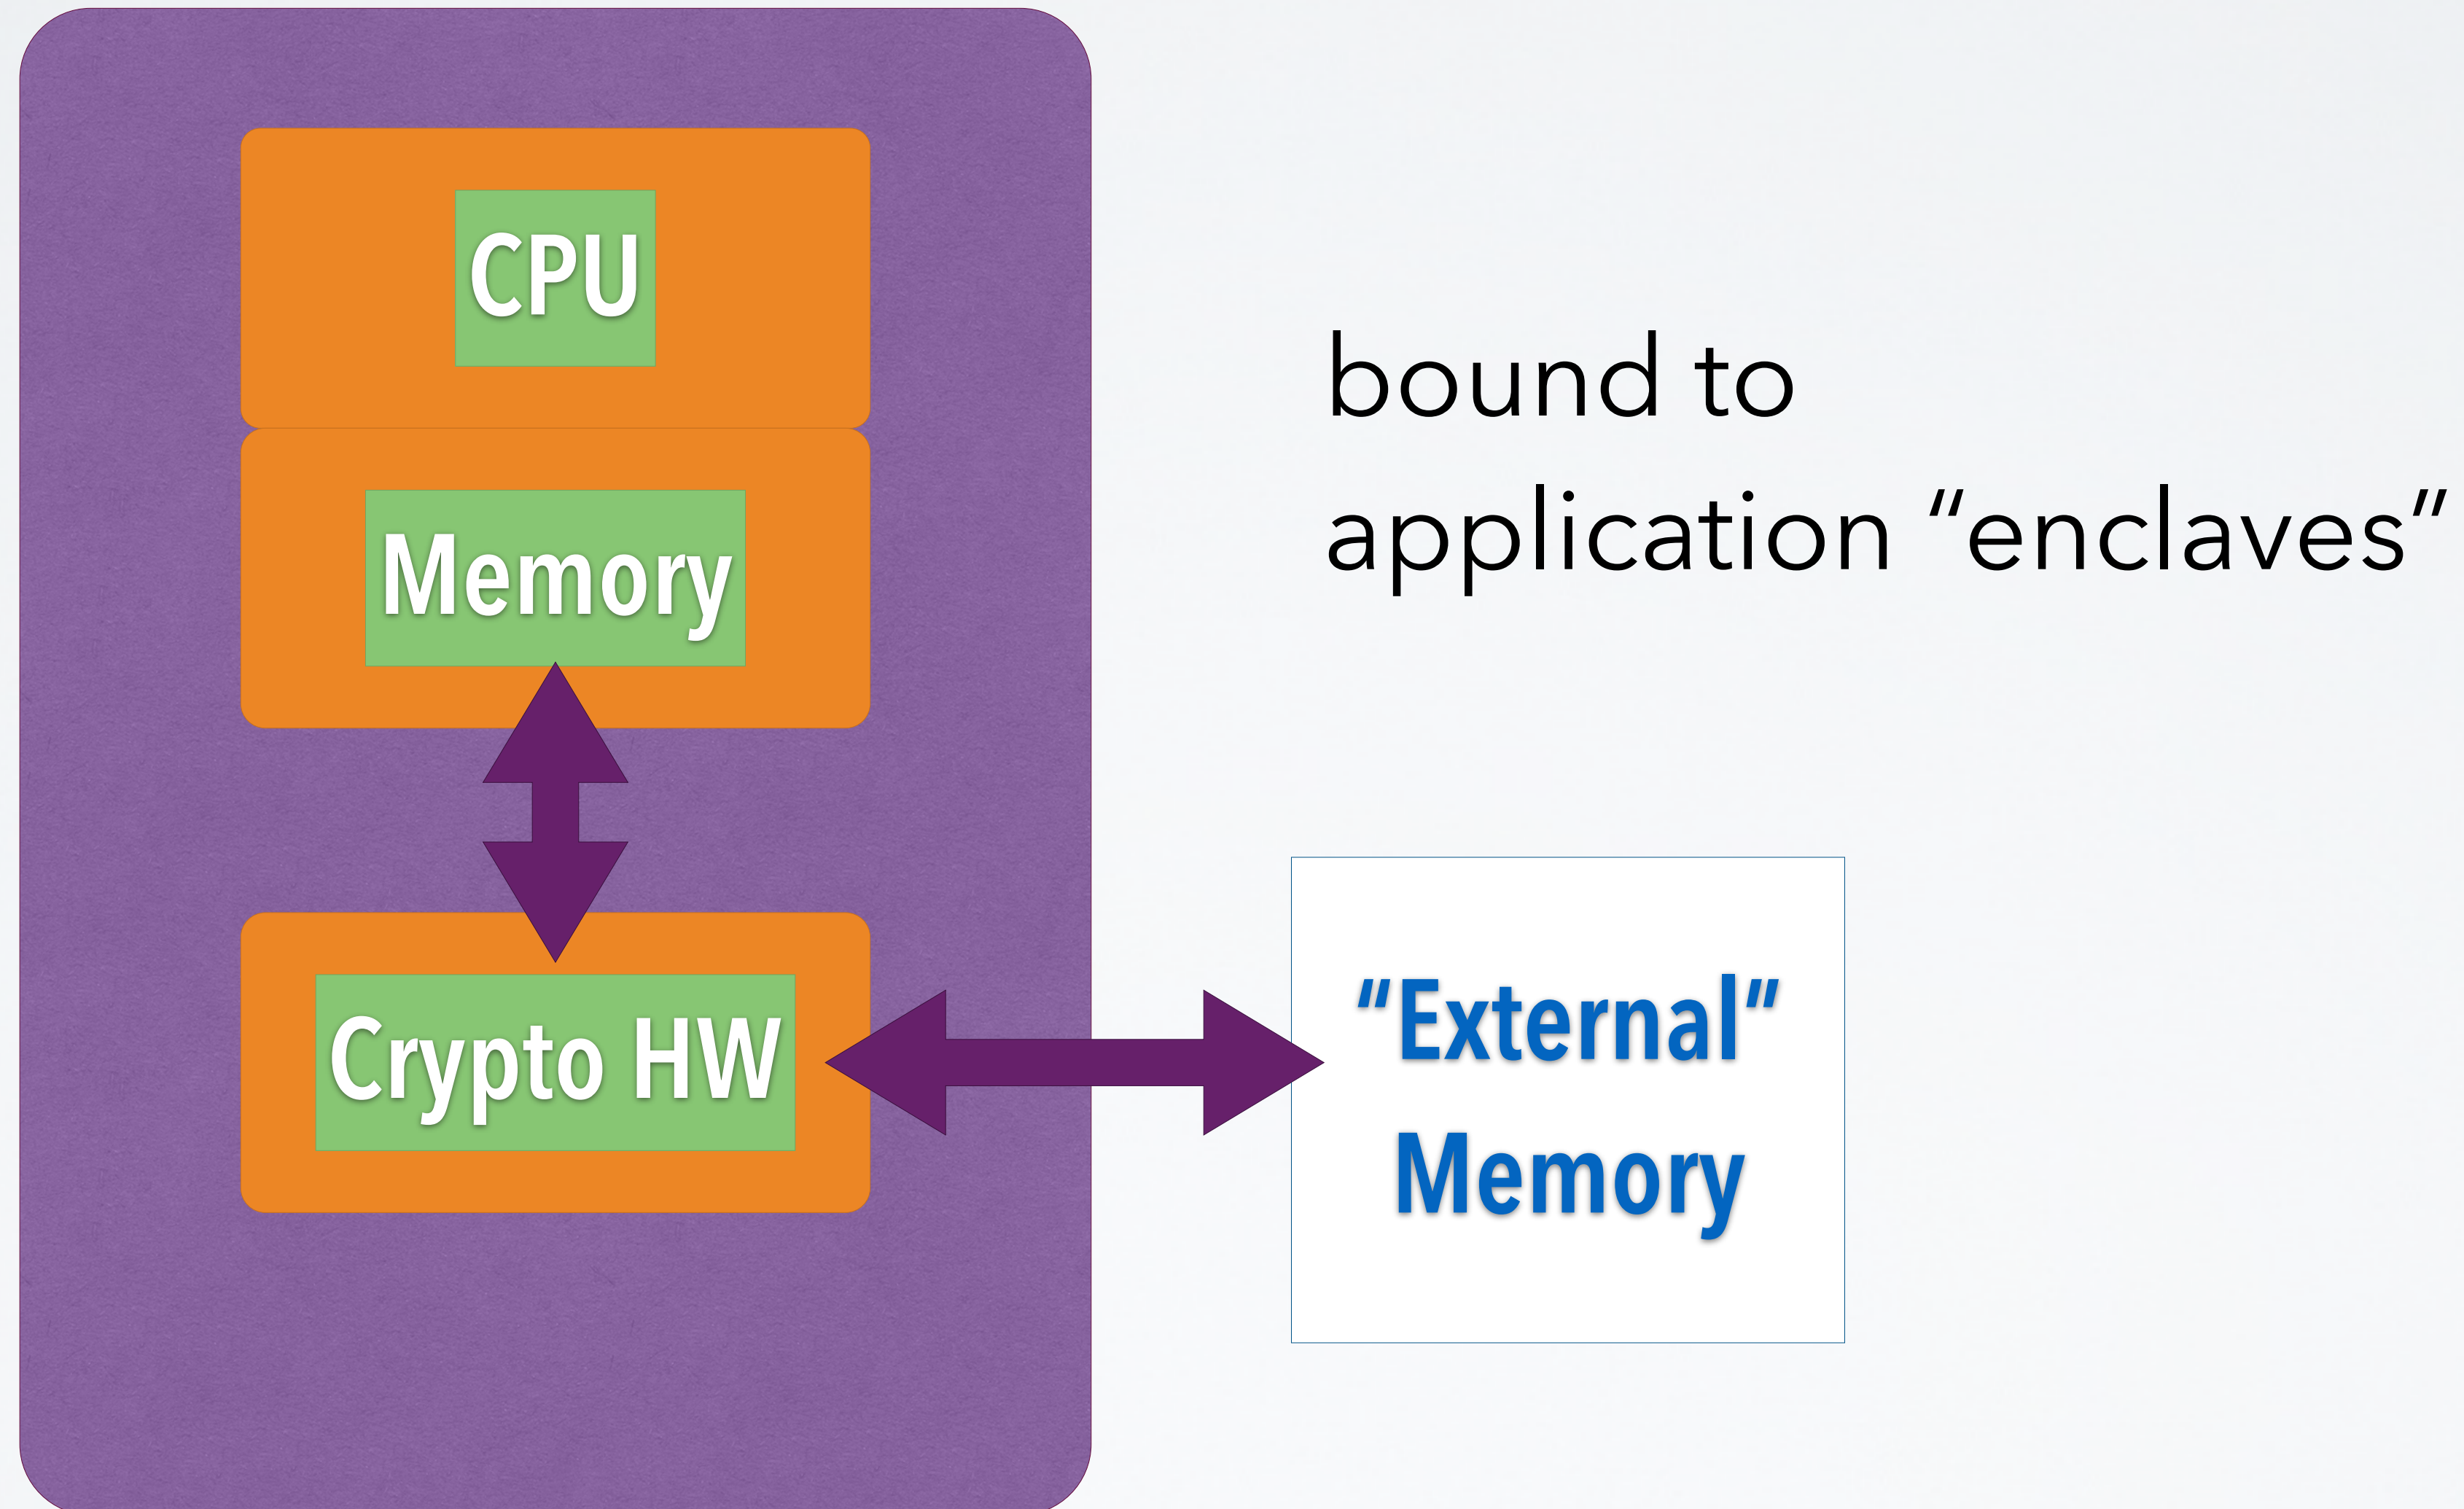

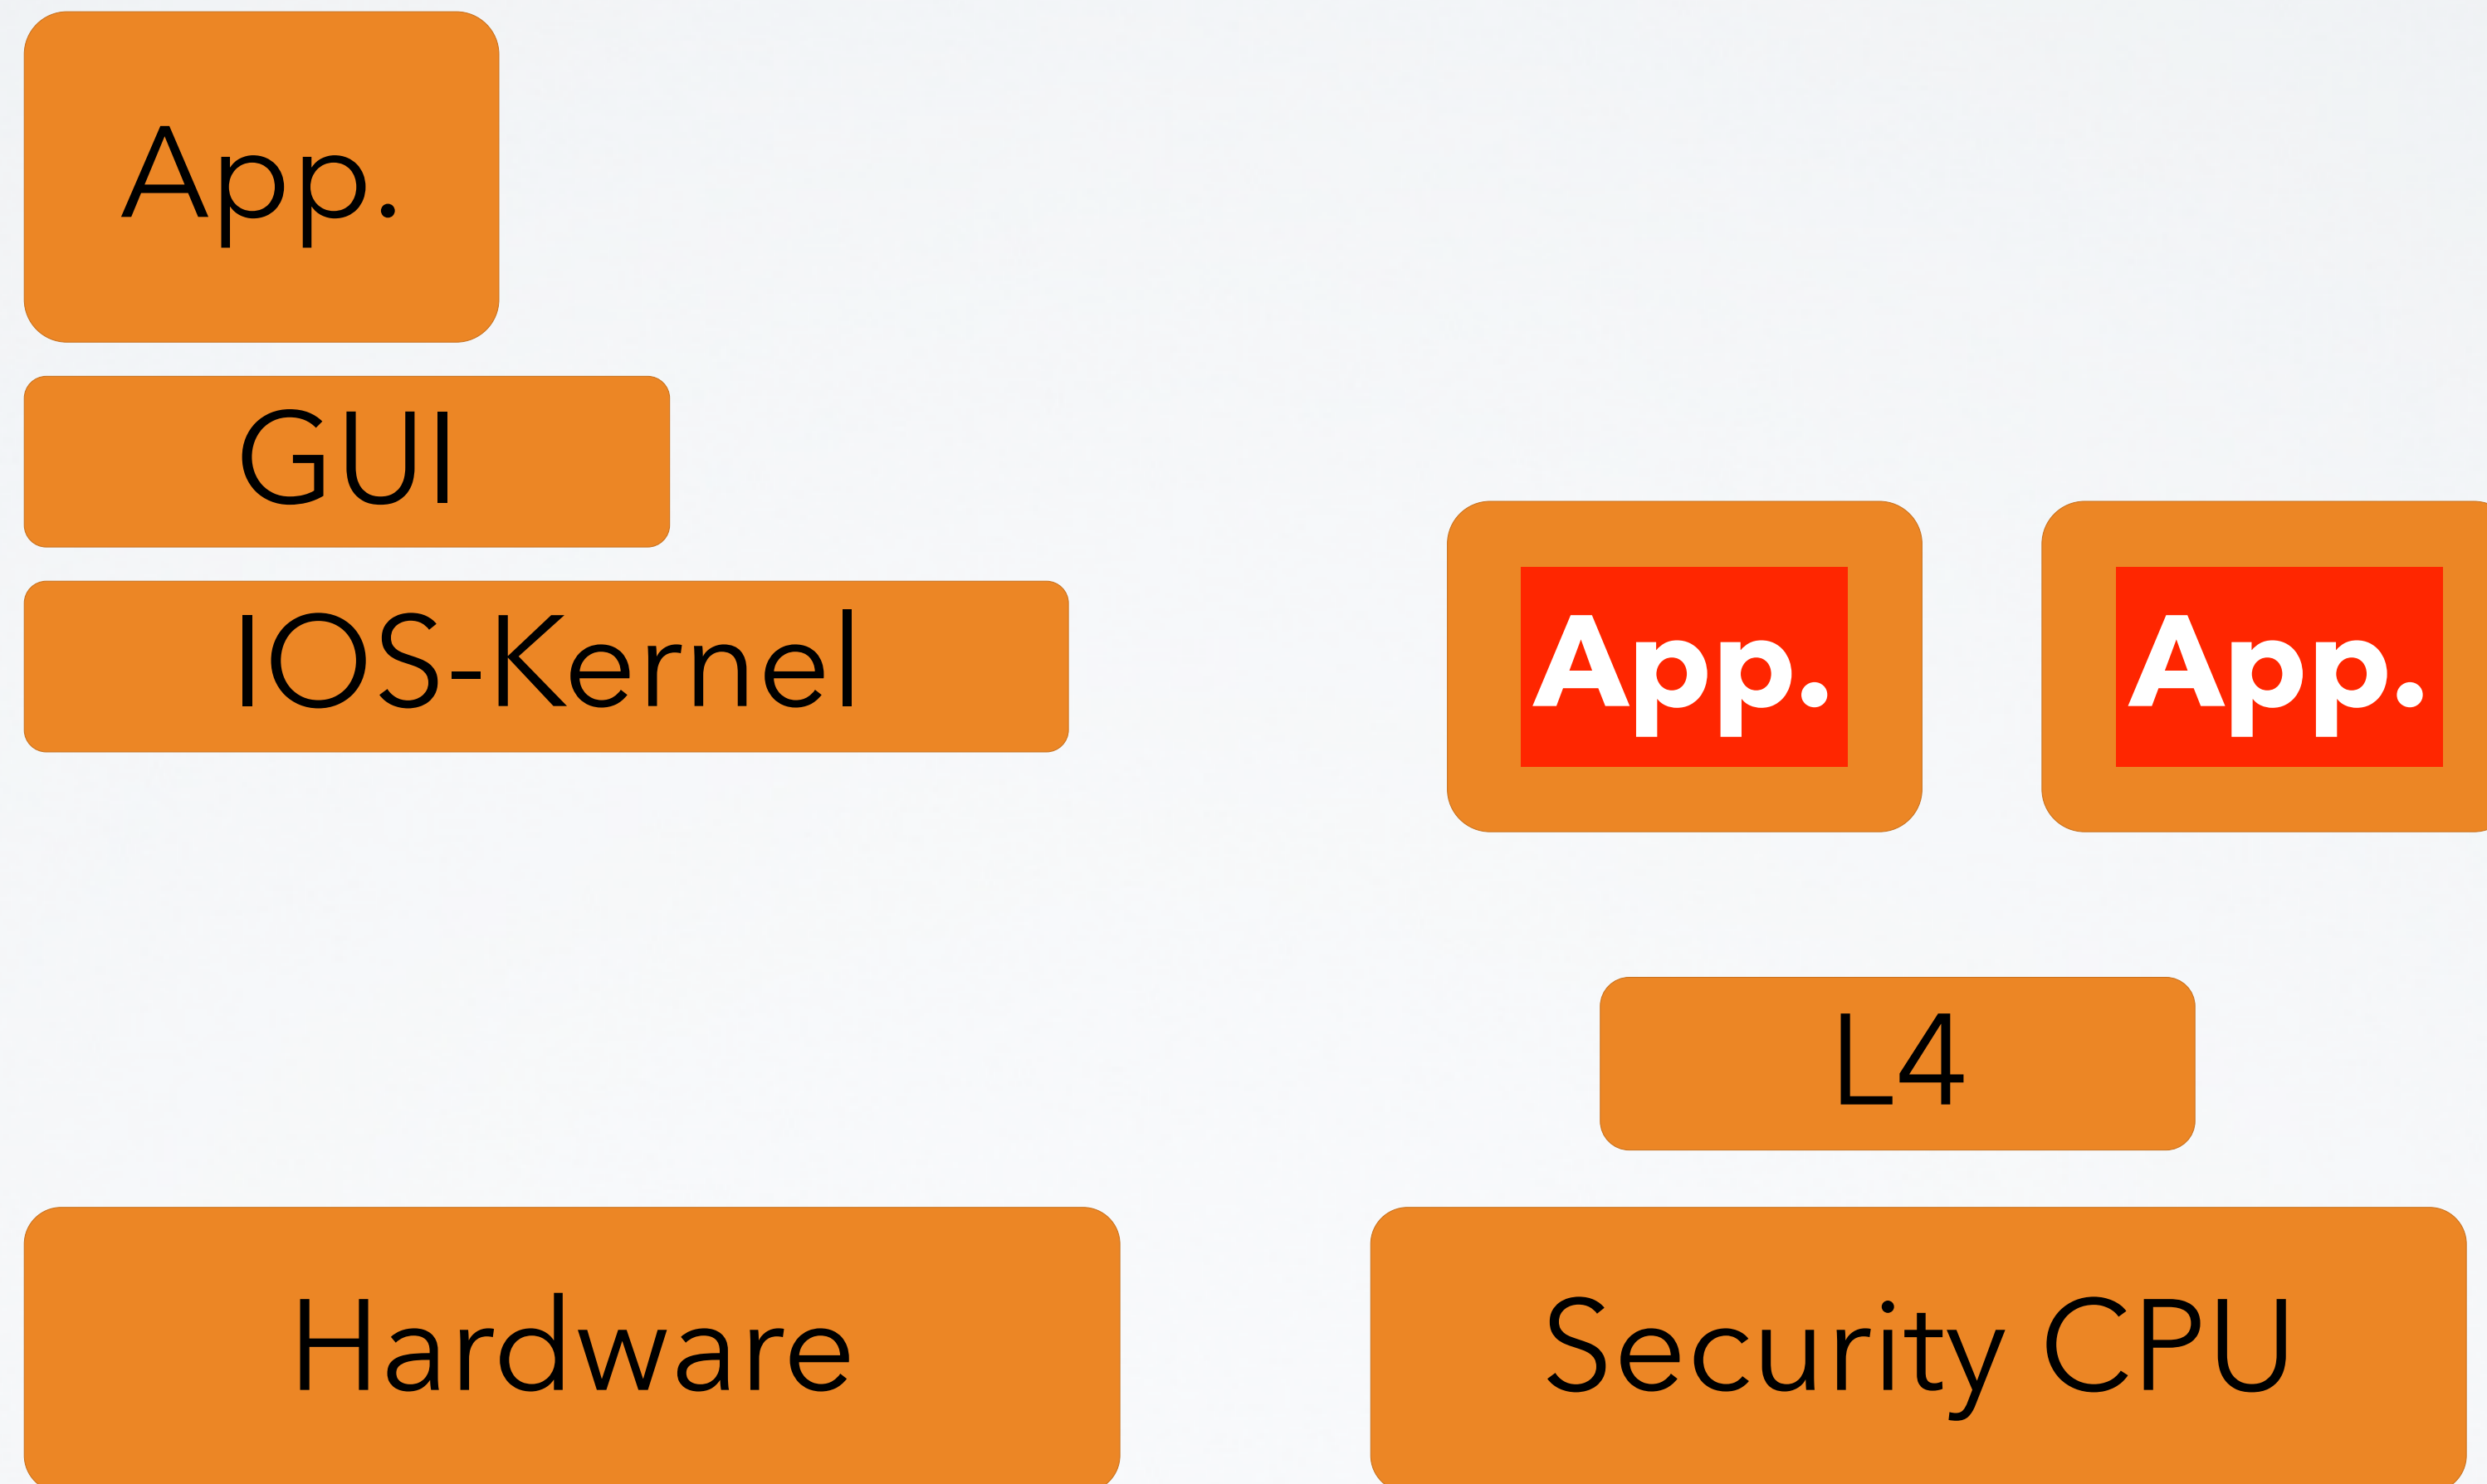

## “Enclaves” for Applications:

- established per special new instruction
- measured by HW
- provide controlled entry points
- resource management via untrusted OS

Important Foundational Paper:

Authentication in distributed systems: theory and practice
